Personality Disorders.—Personality disorders are a group of conditions in which there are persisting patterns of inadequate or antisocial behaviour rather than of predominantly psychological or emotional disturbances that cause suffering and a sense of distress. Persons who always react with undue excitability and ineffectiveness in the presence of minor stress or who regularly display judgment that is not dependable are among those classified as having personality disorders. Such persons have little control over their hostile feelings, are fickle in their relations with others and are unable to form enduring or satisfactory relationships. Vocationally and socially these persons do poorly, even though they may be of normal or superior intelligence and physically well-endowed. Also included in the group with personality disorders are persons who exhibit extreme emotional instability characterized by explosive outbursts of rage upon minor provocation. At times, these personalities may be blustering and threatening; at other times they can be despairing and inaccessible. Two other common forms of personality disorder are seen in persons exhibiting either passive dependence reactions or passive aggressive reactions. The former are generally helpless, indecisive and clinging. When faced with minor problems, they show anxious and panic-stricken behaviour. In contrast, the passive aggressive person expresses his hostility in stubbornness, procrastination and inefficiency.

One of the most complex groups of the personality disorders is the category of sociopaths. Persons with sociopathic tendencies act out their hostility on the rest of the world. As a group they make up the mass of the criminals and delinquent elements of society. Their symptomatology may also include various kinds of pathology expressed in sexual deviations. The commonest expression of this is homosexuality, but there are other forms such as exhibitionism, voyeurism, masochism and sadism. (See also HOMOSEXUALITY; SEXUAL DEVIATIONS.)

Psychophysiological Disorders.—In the psychophysiological disorders, also designated psychosomatic conditions, anxiety produces a dysfunction in bodily organs through inappropriate activation of the involuntary nervous system and the glands of internal secretion. Thus the psychosomatic symptom emerges as a physiological concomitant of an emotional state. For example, in a state of rage the angry man's blood pressure is likely to be elevated and his pulse and respiratory rate to be increased. When the anger passes, the heightened physiologic processes usually subside. However, if the man had a persistent inhibited aggression (chronic rage) which he was unable to express overtly, the emotional state remains unchanged, though unexpressed in the overt behaviour and the physiological symptoms associated with the angry state persist. With time, such a person becomes aware of the physiological dysfunction. Very often he develops concern over what appears as an inappropriate activation of body organs but he will deny or be unaware of the emotions which evoke the reactions. See above, *History: Modern Schools: Psychosomatic Medicine.*

III. TREATMENT OF MENTAL DISORDERS

1. Psychopharmacology.—One of the most striking advances in the symptomatic treatment of mental illnesses in the middle of the 20th century was the development of the series of pharmacological agents commonly known as tranquilizers. These drugs contrast sharply with the hypnotic and sedative drugs that formerly were in use and that clouded the patient's consciousness and impaired his motor and perceptual abilities. The tranquilizers can allay the symptoms of anxiety and reduce agitation with much less disturbance of consciousness. However, valuable as the tranquilizing substances have been, there is need for further study of their effects alone and in combination with other drugs; also drugs with extended and improved properties should be developed. Occasionally the tranquilizing drugs have toxic side effects, giving rise

to such conditions as jaundice or a parkinsonianlike reaction; both these symptoms are reversible upon withdrawal of the drug. The drugs produce other minor symptoms because of their action on the autonomic nervous system.

Tranquilizers are used in treating many different kinds of disturbances but are particularly effective in relieving the symptoms of tension, overactivity, agitation, impulsiveness, explosive outbursts and destructive behaviour. Since they are prescribed for symptoms, they are not specific to the treatment of any diagnostic category. They have been more useful in treating the various psychotic states than in psychoneurotic reactions and personality disorders. The drugs also have been used in the treatment of toxic delirious states resulting from overuse of alcohol and in mental conditions resulting from brain damage.

Because of their ability to modify the behaviour of even the most disturbed patients, these agents have affected greatly the management of the hospitalized mentally ill. They have been responsible for dramatic changes in the behaviour of many psychotic patients. The noisy, untidy, crowded and unpleasant atmosphere that formerly pervaded the wards of many mental hospitals has largely disappeared; in the absence of the destructiveness, apathy and untidiness formerly exhibited by many patients, hospitals can be maintained more attractively. Because of the quieting effects of the tranquilizers, hospital staffs are able to devote more of their attention to other therapeutic efforts, and patients have been given greater freedom to move about and much more rehabilitative assistance. (See also NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY; TRANQUILIZING DRUGS.)

2. Shock Therapy.—In 1933, Manfred Sakel of Vienna presented the first report of his work with insulin shock. Until the discovery of the superiority of the tranquilizing agents, variations of insulin shock therapy (also called insulin coma therapy) were commonly used in the treatment of schizophrenia and other psychotic conditions. With insulin shock treatment, the patient is given increasingly large doses of insulin which reduce the sugar content of the blood and bring on a state of coma. Usually the comatose condition is allowed to persist for about an hour, at which time it is terminated by administering warm salt solution via stomach tube or by intravenous injection of glucose. Insulin shock had its greatest effectiveness with schizophrenic patients whose illness had lasted less than two years (the rate of spontaneous recovery from schizophrenia also is highest in the first two years of the illness). Insulin shock therapy also had more value in the treatment of paranoid and catatonic schizophrenia than in the hebephrenic types.

Electroconvulsive therapy, introduced in Rome in 1938 by U. Cerletti and L. Bini, has been widely used in treating disturbances in which severe depression is the predominant symptom. It has been particularly recommended for manic-depressive psychoses and other types of depression. The technique is essentially the passage of alternating currents through the head between two electrodes placed over the temples. The passage of the current causes an immediate cessation of consciousness and the induction of a convulsive seizure. In general, electroconvulsive treatments are given three times a week for a period ranging from two to six weeks; some acutely disturbed patients, however, have been given as many as two or three treatments in a single day.

Following a course of treatment there is usually an impairment of memory, varying from a slight tendency to forget names to a severe confusional state. The memory defect diminishes gradually over several months. Electroconvulsive therapy, like insulin shock, declined in use after the tranquilizing drugs were introduced.

3. Psychosurgery.—The first treatment of mental disturbances by means of brain surgery was developed by the Portuguese neurologist António C. Egas Moniz (*q.v.*), the first operation being performed by Egas Moniz' colleague Almeida Lima, in 1935. The operation, called prefrontal lobotomy or leucotomy, was based on experimental studies demonstrating that certain neurotic symptoms induced in chimpanzees could be modified by cutting brain fibres. Egas Moniz' original operation consisted of cutting two openings in the skull, one on each side above the temple, and

then severing the nerve fibres connecting the thalamus with the frontal lobes of the brain.

Prefrontal lobotomy has come to be generally regarded as a radical procedure to be followed only after all other forms of treatment have proved ineffective, and since the introduction of the tranquilizing agents the condition of only a very few patients warrants such a drastic measure. Patients selected for this operation usually show chronic agitation and severe distress, persistent depression, emotional aggressiveness and excited and impulsive behaviour. Phobias, obsessions, hallucinations and delusions not of long-standing duration have been relieved by this procedure. On the other hand, psychosurgery has had relatively little effect in modifying behaviour that characteristically expresses cruelty, avoidance of responsibility, excessive use of alcohol or pathological sexuality; it also has proved generally ineffective in the treatment of the chronic and withdrawn psychotic. The procedure tends to accentuate difficult personality traits by lowering inhibitory controls and by leading to development of facetious and tactless social behaviour. Many patients after the operation tend to show increase in self-esteem coupled with lack of self-criticism.

The effect of lobotomy on intellectual functions has been a subject of much controversy. Ordinary psychological tests and observations reveal little change in the patient's psychological functioning in the months immediately following the operation. It is believed, however, that lobotomy results in significant deterioration in intellect over the course of years. Patients who prior to their illness possessed the ability to perform tests requiring a high degree of abstraction showed great impairment in these capacities after lobotomy. Also, close observation of performance of persons with high intellectual capacity indicates a reduction in such capacity after surgery.

4. Psychotherapy.—Psychotherapy is the treatment of personality disturbances by psychological means. The essential factor in the many different techniques of psychotherapy is the establishment of an understanding and accepting relationship between therapist and patient. In this relationship, the therapist does not deprecate, censure or judge the patient, and the patient is encouraged to discover and speak of his emotional life. This is necessary if the aim of treatment is greater insight into the sources of the patient's difficulties and his achievement of greater personal satisfactions. There are many types of psychotherapy, and the indications for their use depend upon a number of variables, including the nature of the illness, age and intellectual capacity of the patient, estimate of his motivation and his capacity to face anxiety. These are discussed in the separate entries PSYCHOTHERAPY; PSYCHOANALYSIS; and PSYCHOLOGY, APPLIED: *Psychology as Applied to Treatment*.

IV. CHILD PSYCHIATRY

The increasing recognition of the crucial influence of parent-child relationships on the child's personality development has provided a strong impetus to the study of psychiatric disorders of childhood. The approach to the diagnosis and treatment of children's mental and emotional disturbances is necessarily different from that with adult patients. The child is living through the most active and critical phases of his development. His personality is constantly being molded and changed as he moves from one developmental stage to another. In assessing the healthy or unhealthy patterns of a child's personality development, the psychiatrist must have extensive knowledge of the ever changing patterns of personality, particularly at the various age levels through adolescence. (See further CHILD PSYCHOLOGY; ADOLESCENCE.)

Although many of the general principles relating to therapy of adult psychiatric disorders apply to child psychiatry, a number of special problems arise with children which require special techniques. Usually the parents of the child bring him for treatment, or he is referred to the psychiatrist by a community agency—the school or the juvenile or family court. Because much of the essential information on the child's behaviour and other medical, psychological and social factors must be obtained from the parents, the pediatrician, psychologist, teacher or social work-

ers, child psychiatrists work closely with the parents and other specialists who have been in frequent or close contact with the child. Thus, in the field of child psychiatry, the working relationship between the psychiatrist and the related social and medical disciplines is closer and more essential than it is in adult psychiatry, where the patient usually can provide much of the pertinent and necessary information on his life and his condition.

For the most part, child psychiatry is concerned with the study and treatment of the different neurotic reactions or problems of emotional maladjustment that affect children. The emotional maladjustments of children frequently are manifested in behaviour difficulties, unpleasant character traits or psychosomatic disturbances. Neurotic reactions include habit spasms, stammering, overactivity and phobias. Ticlike movements of the face and other parts of the body are common. Among infants, deprivation of mothering or problems in the infant's relationship with the mother may lead to withdrawn behaviour, continuous crying, inability to eat, insomnia and physical or mental retardation or both. Older children are often seen for such habit disturbances as persistent nail biting, thumbsucking, bedwetting and temper tantrums. Children also are referred for treatment because of conduct problems or propensities for disobedience, lying, stealing, destructiveness, fighting, fire setting, cruelty and running away from home.

As in the treatment of adult patients, psychiatric treatment of children requires determination of any genetic, constitutional or physical factors that have contributed to the disturbance. Also, it is essential that the relationship between the child and the parent be assessed for its contribution to the disturbed behaviour. Where there are disturbing influences that can be associated with parental dissension, alcoholism, hostility, cruelty, neglect, overprotection of the child, excessive ambitions for and expectations of the child, it is common to find behavioural disorders. The existence of neurotic, psychotic or psychopathic illness in the parents also contributes to a faulty parent-child relationship. The parents' unconscious feelings about the child and the kinds of conflicts which disturb the parent-child relationship also must be determined. (It must be recognized that the emotional behaviour of the parents is sometimes the result rather than the cause of the child's misdemeanours.) Another important source of personality problems is the child's relationship with brothers and sisters. In addition, the death or loss of a parent often has a profound and lasting effect, as it reduces the child's opportunity for healthy growth through continuing identification with or differentiation from the absent parent.

School experiences also can create personality problems. Many children exhibit conduct and learning disturbances because they have been unable to cope with modern methods of instruction. Children with perceptual difficulties, for example, may fail to learn to read or may not develop the reading skills appropriate to their age level, because of the scanning method of teaching reading without phonetic sounds or spelling out the letters in a word. As a consequence, they often become anxious over their failure to meet the standards of their family and their class. When these emotions are aroused, conduct disturbances may ensue.

V. PSYCHIATRIC TRAINING AND ORGANIZATION

A. TRAINING

1. United States.—In the United States, to qualify as a specialist in psychiatry, a physician must complete a period of training in an accredited or qualified hospital or other institution. Usually the physician enters a psychiatric residency training program after one year of medical internship, which followed his obtaining the degree of doctor of medicine from an accredited medical school. Residency training in psychiatry provides supervised experience in the diagnosis and treatment of mental and emotional illnesses. It includes opportunities for using all the varieties of treatment in specialized psychiatric hospitals and institutions, out-patient departments, various kinds of children's services and general hospitals. The resident physician in psychiatry also is required to take formal course work in such fields

as psychobiology, psychopathology and psychodynamics, neuroanatomy, neurophysiology and neuropathology. Upon completion of this training, the physician may apply for examination by the American Board of Psychiatry and Neurology. The certificate of the board indicates that the physician has completed his general training; it does not measure his level of competence in the performance of special therapies.

The clinical psychologist, in contradistinction to the specialist in psychiatry, is not trained in medicine. He has the degree of doctor of philosophy in psychology and has been trained in the theory and practice of psychological testing of mental patients. In some institutions he may, under supervision, receive training to do certain forms of psychotherapy. The training of the clinical psychologist, unlike that of the psychiatrist, does not equip him to diagnose, to prescribe drugs and medicine, or to administer shock therapy and other psychiatric diagnostic and treatment procedures.

For the most part, the psychoanalyst in the United States has obtained the degree of doctor in medicine and has completed a residency in psychiatry. In addition, he has completed the requirement of a personal psychoanalysis and has conducted the analysis of several patients under the supervision of a qualified training analyst. Also he has undertaken and completed certain other didactic and clinical training. The majority of qualified psychoanalysts in the United States are members of or candidates for membership in the American Psychoanalytic association.

A small group of clinical psychologists, social workers and others also have been trained to do psychotherapy and psychoanalysis. These persons were trained largely in the past by psychoanalysts in England and other western countries of Europe. The U.S. medical profession generally believes that clinical psychologists, social workers and lay analysts who practise psychotherapy or psychoanalysis should do so in collaboration with a psychiatrist or a physician. This position is based on the belief that proper psychiatric diagnosis requires a physical and neurological examination; only those trained in medicine are able to decide whether the somatic symptoms of an illness are due to an underlying physical process or are representative of an emotional disturbance. On the other hand, psychologists and other non-medical persons trained in psychoanalysis have made many fundamental and valuable contributions toward the elucidation of the basis of behaviour and the understanding of personality development.

2. Great Britain.—In Great Britain the physician may begin his training for the specialty of psychiatry after he has completed his preregistration appointments and his national service. He then serves on the staff of a mental hospital for a minimum of two years, at which time he may be examined for the diploma in psychological medicine (D.P.M.) by the Conjoint board. The D.P.M. does not qualify the recipient as a consultant in the national health service; such senior appointments are approved by a committee of outstanding specialists, who judge the candidate in competition with others applying for the post.

The teaching program of the Institute of Psychiatry of the British Postgraduate Medical federation conducted at the Maudsley and Bethlem Royal hospitals in London is similar to that of the best residency programs in the United States. In terms of formal scholarship, the British institute is more exacting than any of the American institutes. The British institute awards its own D.P.M., which has higher standards and requires more extensive training than the certificate of the Conjoint board. While the British institute is the only fully developed British university postgraduate centre in psychiatry, Great Britain has other institutes, hospitals and clinics in which special kinds of psychiatric training can be obtained. The Institute of Psychoanalysis in London provides specialized training much like that of the psychoanalytic institutes and training centres in the United States.

3. Other Countries.—In Canada, although each province makes its own arrangements for awarding diplomas in psychiatry, the training of the physician specializing in psychiatry is much like that of the psychiatrist trained in the United States. The training of psychiatrists in Australia and New Zealand is similar

to English psychiatric training. South Africa has modeled its training program in psychiatry closely after that of the Netherlands. There, to become registered as a specialist psychiatrist or specialist in mental disorders, the applicant must be qualified as a medical practitioner for at least six years, and must satisfy certain clinical requirements in medicine and surgery as well as in psychiatry. Upon fulfilling these requirements satisfactorily, he obtains a higher degree in his specialty. Several universities in India award a diploma in psychological medicine.

B. ORGANIZATIONS

1. United States.—The American Psychiatric association, oldest national medical association in North America, was founded in 1884, and in the mid-1960s had a membership of more than 10,000 psychiatrists. The organization has an information service, and publishes several journals as well as a biographical directory of its members. Its aims are the improvement of treatment of the mentally ill and the furtherance of psychiatric education and research.

The National Institute of Mental Health of the United States public health service is the major federal government agency concerned with the prevention and treatment of psychiatric disorders. Through the provisions of the National Mental Health act of 1946, the institute makes grants-in-aid to support training, research and community services in the United States. The institute also conducts an extensive research program at the National Institutes of Health in Bethesda, Md.

2. Great Britain.—Under the Mental Health act, 1959, the Board of Control for England was dissolved and mental health was administered by the minister of health advised by a standing mental health committee. The act established a review tribunal for each of 15 regions, under the direction of the lord chancellor. These tribunals were convened at times provided by the act, when certain patients detained against their will could make application to be heard. In Scotland the function of the Board of Mental Welfare (formerly the General Board of Control) is chiefly the control and treatment of patients.

In England, the major professional psychiatric organization is the Royal Medico-Psychological association. Similar professional bodies have been established throughout the British commonwealth. The Canadian Psychiatric association, chartered in 1951 and associated with the Canadian Medical association, has more than 600 members. Since most matters related to the practice of medicine fall within the jurisdiction of the provincial governments in Canada, the Canadian Psychiatric association has been active in developing its relations with these governments.

3. Other Countries.—Psychiatrists of Australia and New Zealand are organized as the Australian Association of Psychiatrists. In India, the psychiatric organization is known as the Indian Psychiatric society. In South Africa the National Group of Neurology, Psychiatry and Neurosurgery represents the aims of the specialty. Each organization supplies information on its aims, its members and the psychiatric facilities of the country. Similar organizations exist in other European and South American countries.

4. International.—International bodies concerned with mental health are discussed in the article MENTAL HEALTH.

PSYCHICAL RESEARCH is the scientific study of such alleged occurrences as thought transference, foretelling the future, hauntings involving appearances of ghosts and movements of objects, and messages received through mediums from the spirits of those who have died. All such alleged events may be included in the class of the paranormal; early subjects of study included hypnotism, which is no longer regarded as paranormal (see HYPNOSIS).

In 1882 the Society for Psychical Research was founded in London, followed six years later by the founding of a similar society in the United States. Such societies were founded later in most European countries, and active work is carried on, particularly in the Netherlands, France, and Italy. Universities have been slower to recognize psychical research as a serious subject for study. The activities of the parapsychological laboratory at Duke University, Durham, N.C., under J. B. Rhine from the 1930s to the 1960s attracted considerable interest. A department of psychical research also was opened at the University of Utrecht under W. H. C. Tenhaeff.

One of the reasons for interest in psychical research in the last half of the 19th century was the rise of the spiritualist movement that grew out of the acceptance of the reality of spirit communication and the use of this as the basis of a new religion. Some of the early psychical researchers were also spiritualists, as, for example, F. W. H. Myers and Sir Oliver Lodge. Other psychical researchers (such as the physiologist C. Richet) accepted paranormal activity as real but rejected the spiritualist explanation, while others were not committed to either view.

Existence After Death.—Advances in psychical research have made the solution of the problem of providing proof of survival after death increasingly difficult. The experimental evidence of the existence of psi cognition (obtaining knowledge by telepathy or clairvoyance) as a paranormal ability among some persons suggests a natural explanation for information apparently coming from spirits. For example, some of the early researchers (e.g., Myers and Lodge) left sealed packages with the intention of communicating the contents after their death. In fact, neither experiment was successful, but if they had succeeded their success might have been explained in terms of the clairvoyant powers of the medium. A modification of such an experiment is an attempt by a medium to communicate the message during the lifetime of the person depositing it; failure during his lifetime followed by success after his death would provide at least some evidence that he was communicating after death. No experiment of this type, however, had been completed by the 1960s.

Soon after Myers' death in 1901 an experimental demonstration of survival was arranged ostensibly from the other side of the grave, presumably by Myers himself. Called cross-correspondence, essentially it was communication, through different mediums, of fragments of a message that made a coherent whole only when fitted together. Success in such a task cannot easily be explained by reference to possible paranormal powers of the medium. Its results are not easy to evaluate, but many respected judges are of the opinion that the cross-correspondences provide strong evidence of the survival of the deceased persons who were their ostensible originators.

Evidence along different lines was sought by Whately Carrington, who applied psychological tests to communicators in the attempt to discover whether a single communicator coming through different mediums showed constant measurable characteristics that would indicate that he was one and the same person. Critical examination of Carrington's results shows that he obtained no evidence of the identity of his communicators. The research method was ingenious, however, and the problem remained to be studied further.

Telepathy.—Much better success has attended the experimental investigation of what is called thought transference or telepathy. The typical form of this experiment is that in which the task is card guessing: an agent turns up and looks at successive cards in a pack of playing cards and a percipient tries to tell him which they are. Promising results were obtained early but critics urged the necessity for further precautions against error before it could be

accepted that a thought could pass from one mind to another without use of the ordinary sensory channels of communication. Further experiments with a different type of card were carried out at Duke University (see PARAPSYCHOLOGY). They were also carried out with increased precautions against error and a good rate of success by S. G. Soal and K. M. Goldney in Great Britain.

In the meantime, however, Rhine had thrown doubt on the appropriateness of regarding these as tests of telepathy, since he found that equal success could be obtained when no one looked at the cards. The performance would then commonly be called clairvoyance. Extrasensory perception (ESP) is a term commonly used now to cover both telepathy and clairvoyance. The more noncommittal term psi has also been suggested to cover all types of paranormal cognition, and is widely used.

There is, from time to time, an arousal of public interest in telepathy through the appearance on the stage of an entertainer who is supposed to demonstrate telepathy. Less frequently the demonstration is of so-called eyeless sight. The resources of stage telepathy have been enlarged by the development of small wireless receiving sets that can be concealed on the person, although impressive demonstrations were given earlier by the use of codes and other methods. Such trick telepathy has no bearing on the question of whether real extrasensory perception takes place. The experimenter has the task of arranging his conditions so that the experimental subject has no opportunity to trick him. Without such precautions, the experiment is of no value as evidence for the reality of the phenomenon under investigation.

Supernatural Foresight.—A form of paranormal cognition for which there is a long tradition of anecdotal evidence is the foreseeing of the future by dreams and by various devices such as looking at the flight of birds or at the entrails of sacrificial animals, or listening to the wind blowing through leaves (see DIVINATION). No important contribution to psychical research has been made by studying any of these devices. On the other hand, experiments have been done in which the percipient's task is to guess the future order of a pack of cards after a process of shuffling and cutting. There seems to be evidence that some subjects can succeed in such a task of precognition, although the level of statistical significance encourages less confidence than that for experimental extrasensory perception.

Physical Manifestations.—Psychical research has also been concerned with paranormal phenomena such as levitation, materialization, and the moving of heavy objects. Sir William Crookes studied both the phenomena of the medium D. D. Home and a materialized figure (Katie King) that developed in the presence of the medium Florence Cook, reporting that he had satisfied himself as to their genuineness. A remarkable medium, an uneducated Italian woman called Eusapia Palladino, exasperated psychical researchers by her crude attempts to cheat if controls were relaxed. A critical experimental study of her, however, by three experienced psychical researchers produced striking physical manifestations under conditions which the experimenters said were such that fraud was impossible.

The most remarkable studies of materializations were made in France by G. Geley and Richet. Wax gloves have been produced that are reported to have been made by spirit hands dipped into molten wax and dematerialized after the wax solidified. There are photographs of ectoplasm, the quasi-material substance that is supposed to be exuded from the medium's body to form the substantial basis for materializations. Many of these photographs show part of the ectoplasmic substance in the shape of human faces or other parts of the human form. These photographs are plainly not in themselves evidence of the reality of ectoplasm, as the wax gloves are not evidence of the reality of materialized hands. In both cases, their weight as evidence depends on the reliability of the persons obtaining them.

Physical manifestations are often lightly dismissed because they can easily be simulated by fraudulent means and are so simulated by dishonest mediums. Their investigation is made difficult by the fact that they are generally produced in darkness or reduced light. At the same time, it should be noticed that those investigators who became convinced of their genuineness were aware of

the possibilities of fraud and were satisfied that their precautions to exclude fraud were adequate. Such experienced scientific investigators as Crookes, Lodge, Sir W. Barrett, and Richet are included in this group.

Spontaneous Phenomena.—In addition to these various experimental lines of investigation, a large field of spontaneous phenomena has engaged the attention of psychical researchers. This field includes apparitions of the living and of the dead and also hauntings. An early inquiry into apparitions revealed that these had little of the appearance of the ghost of fiction. They were not vague sheeted figures, but of the form and appearance of living persons, for whom they were often mistaken. It has been argued that there is little reason for regarding them as spirits but rather as hallucinatory perceptual experiences which may originate from a genuinely paranormal process. It was argued that apparitions of persons near the point of death occurred too often for the coincidence between death and the apparition to be entirely a chance coincidence.

Spontaneous reports of hauntings suggest that these are of two main types: that in which an apparition is repeatedly seen in the same place and that in which the main phenomena are noises and displacement of household objects. A good example of the former type is the apparition described by a woman who wrote in the *Proceedings of the Society for Psychical Research* (vol. viii, 1892) under the pseudonym of Miss Morton. This apparition was said to be constant in form, stereotyped in action, seen only occasionally and never when watched for. It was reportedly sometimes seen by more than one person at the same time, but also it might be seen by one person and not by another who was also present; it could apparently be seen by domestic animals. The reported visual experiences differed, therefore, from the perception of a physical object and also from an autogenic hallucination. Various theories have been put forward, but the data on hauntings are neither full enough nor sufficiently systematically collected to make it possible to subject alternative theories to critical tests.

Haunting characterized by noise and displacement of objects is commonly called a poltergeist haunting, and cases have been reported for a long time. Epworth rectory, Lincolnshire, the home of Charles Wesley, was the reputed scene of such phenomena, and W. Barrett reported the opportunity of observing and recording similar events at Derrygonnelly farm.

Poltergeist reports at different times and different places show a curious parallelism. One feature that nearly all have in common is that the phenomena occur in the presence of a young person, boy or girl, somewhere between the ages of 12 and 20. This fact led many of the early observers to suppose that all poltergeist phenomena were products of normal mischief; or (whether normal or paranormal) are products of emotional strain in the young person concerned. Various theories have been put forward to account for poltergeist phenomena, many of which have little evidential support. A fuller understanding must await a closer study of such cases with the use of modern recording devices. Sensational newspaper stories of poltergeist phenomena are not to be regarded as a safe basis for any kind of theory.

PSYCHOANALYSIS. The first part of this article, written by Sigmund Freud and lightly revised, appeared in 1926. It describes the development of psychoanalysis and its nature as therapeutic method and psychological theory, and evaluates its status at that date. The latter parts of the article treat of subsequent developments in psychoanalytic theory and practice into the second half of the 20th century, and the influence of psychoanalysis on the arts (especially literature) and social thought.

FUNDAMENTALS

In the years 1880-82 a Viennese physician, Josef Breuer (*q.v.*), discovered a new procedure by means of which he relieved a girl, who was suffering from severe hysteria, of her symptoms. The idea occurred to him that the symptoms were connected with impressions which she had received during a period of excitement while she was nursing her sick father. He therefore induced her, while she was in a state of hypnotic somnambulism, to search for these connections in her memory and to live through the "pathogenic" scenes once again without inhibiting the affects that arose in the process. He found that when she had done this the symptoms disappeared for good.

This was at a date before the investigations of J. M. Charcot and Pierre Janet (*q.v.*) into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud (*q.v.*): In 1895 they published a book, *Studien über Hysterie*, in which Breuer's discoveries were described and an attempt was made to explain them by the theory of *catharsis*. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation (*conversion*). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path (*abreaction*). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were dependent on the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term *psychoanalysis*, which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as "depth psychology."

Subject Matter of Psychoanalysis.—Psychoanalysis finds a constantly increasing amount of support as a therapeutic procedure, because of the fact that it can do more for certain classes of patients than any other method of treatment. The principal field of its application is in the milder neuroses—hysteria, phobias and obsessional states—but in malformations of character and in sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type. In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training, and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by results. Psychoanalysis does not act as a convenient panacea (*cito, tuto, jucunde*, "quickly, safely, pleasantly") upon all psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections.

The therapeutic results of psychoanalysis depend upon the replacement of unconscious mental acts by conscious ones and are operative in so far as that process has significance in relation to the disorder under treatment. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psychoanalysis as the science of the unconscious than as a therapeutic procedure.

Depth Psychology.—Psychoanalysis, in its character of depth psychology, considers mental life from three points of view: the dynamic, the economic, and the topographical.

The Dynamic Standpoint.—From the first of these standpoints, the dynamic one, psychoanalysis derives all mental processes (apart from the reception of external stimuli) from the interplay

of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of *instincts*; that is to say, they have an organic origin. They are characterized by possessing an immense (somatic) persistence and reserve of power (*repetition-compulsion*), and they are represented mentally as images or ideas with an affective charge (*cathexis*). In psychoanalysis, no less than in other sciences, the theory of instincts is an obscure subject. An empirical analysis leads to the formation of two groups of instincts: the so-called ego instincts, which are directed toward self-preservation, and the object instincts, which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego instincts and object instincts; namely, (1) Eros, the instinct which strives for ever closer union, and (2) the instinct for destruction, which leads toward the dissolution of what is living. In psychoanalysis the manifestation of the force of Eros is given the name *libido*.

The Economic Standpoint.—From this point of view, psychoanalysis supposes that the mental representations of the instincts have a cathexis of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming up of these energies and to keep as low as possible the total amount of the excitations to which it is subject. The course of mental processes is automatically regulated by the *pleasure-pain principle*, and pain is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the *reality principle*, whereby the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of pain.

Mental Topography.—Topographically, psychoanalysis regards the mental apparatus as a composite instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psychoanalytic views, the mental apparatus is composed of an *id*, which is the reservoir of the instinctive impulses; of an *ego*, which is the most superficial portion of the id and one which is modified by the influence of the external world; and of a *superego*, which develops out of the id, dominates the ego and represents the inhibitions of instinct characteristic of man. Further, the property of consciousness has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

At this point two observations may be in place. It must not be supposed that these very general ideas are presuppositions upon which the work of psychoanalysis depends. On the contrary, they are its latest conclusions and are in every respect open to revision. Psychoanalysis is founded securely upon the observation of the facts of mental life, and for that very reason its theoretical superstructure is still incomplete and subject to constant alteration. Second, there is no reason for astonishment that psychoanalysis, which was originally no more than an attempt at explaining pathological mental phenomena, should have developed into a psychology of normal mental life. The justification for this arose with the discovery that the dreams and mistakes (*parapraxes*, such as slips of the tongue, etc.) of normal men have the same mechanism as neurotic symptoms.

Theoretical Basis.—The first task of psychoanalysis was the elucidation of nervous disorders. The analytical theory of the neuroses is based upon three ground pillars: the recognition of (1) repression, (2) the importance of the sexual instincts, and (3) transference.

Censorship.—There is a force in the mind which exercises the functions of a censorship, and which excludes from consciousness and from any conscious influence upon action all tendencies which displease it. Such tendencies are described as "repressed." They remain unconscious, and if the physician attempts to bring them into the patient's consciousness he provokes a *resistance*. These repressed instinctual impulses, however, are not always made pow-

erless by this process. In many cases they succeed in making their influence felt by circuitous paths, and it is the indirect or substitutive gratification of repressed impulses that constitutes neurotic symptoms.

Sexual Instincts.—For cultural reasons the most intensive repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive gratifications of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extrauterine existence; it reaches a first culminating point at or before the fifth year (early period), after which it is inhibited or interrupted (latency period) until the age of puberty, which is the second climax of its development. This double onset of sexual development seems to be distinctive of the genus *Homo*. All experiences during the first period of childhood are of the greatest importance to the individual, and, in combination with his inherited sexual constitution, form the dispositions for the subsequent development of character or disease. It is a mistaken belief that sexuality coincides with "genitality." The sexual instincts pass through a complicated course of development, and it is only at the end of it that the "primacy of the genital zone" is attained. Before this there are a number of "pregenital organizations" of the libido—points at which it may become "fixated" and to which, in the event of subsequent repression, it will return (*regression*). The infantile fixations of the libido determine the form of neurosis which sets in later. Thus the neuroses are to be regarded as inhibitions in the development of the libido.

The Oedipus Complex.—There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations; that is, upon the relative strength of the forces concerned. The most important conflict with which a small child is faced is his relation to his parents, the *Oedipus complex*; it is in attempting to grapple with this problem that persons destined to suffer from a neurosis habitually fail. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this probably holds true not only in the life of individuals but also in the history of the human species as a whole. The superego, the moral factor which dominates the ego, also has its origin in the process of overcoming the Oedipus complex.

Transference.—By transference is meant a striking peculiarity of neurotics. They develop toward their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations toward their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named *suggestion*, and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psychoanalytic treatment acts as a second education of the adult, as a correction to his education as a child.

Within this narrow compass it has not been possible to mention many matters of the greatest interest, such as the *sublimation* of instincts, the part played by symbolism, the problem of *ambivalence*, etc. Nor has there been space to allude to the applications of psychoanalysis, which originated, as has been seen, in the sphere of medicine, to other departments of knowledge (such as anthropology, the study of religion, literary history, and education) where its influence is constantly increasing. It is enough to say that psychoanalysis, in its character of the psychology of the deepest unconscious mental acts, promises to become the link between psychiatry and all of these other fields of study.

The Psychoanalytic Movement.—The beginnings of psychoanalysis may be marked by two dates: 1895, which saw the publication of Breuer and Freud's *Studien über Hysterie*, and 1900, which saw that of Freud's *Traumdeutung*. At first the new discoveries aroused no interest either in the medical profession or

among the general public. In 1907 the Swiss psychiatrists, under the leadership of E. Bleuler and C. G. Jung (*qq.v.*), began to concern themselves in the subject, and in 1908 there took place at Salzburg a first meeting of adherents from a number of different countries. In 1909 Freud and Jung were invited to the United States by G. Stanley Hall to deliver a series of lectures on psychoanalysis at Clark University, Worcester, Mass. From that time forward interest in Europe grew rapidly; it showed itself, however, in a forcible rejection of the new teachings, characterized by an emotional colouring which sometimes bordered upon the unscientific.

The reasons for this hostility are to be found, from the medical point of view, in the fact that psychoanalysis lays stress upon psychical factors, and, from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality such importance as is assigned to it by psychoanalysis. In spite of this widespread opposition, however, the movement in favour of psychoanalysis was not to be checked. Its adherents formed themselves into an international association which survived World War I, and by 1926 there were psychoanalytic societies in Vienna, Berlin, Budapest, London, Switzerland, the Netherlands, Moscow, Calcutta, and two in the United States. There were psychoanalytic polyclinics in Vienna, Berlin, and London, and several training institutes were in process of organization. At that time, too, three journals were the official organs of the societies on the continent and in England: the *International Zeitschrift für Psychoanalyse*, *Imago* (concerned primarily with applications of psychoanalysis to nonmedical fields), and the *International Journal of Psychoanalysis*. (S. Fr.)

LATER DEVELOPMENTS

Freud himself, before his death in 1939, wrote major contributions to psychoanalytical theory and its applications. His *Inhibitions, Symptoms and Anxiety* (1926; see bibliography) gave anxiety a key position in psychopathology, relating it to ego activity and defense against instinct. *The Problem of Lay Analyses* (1926) covers a much wider field than its title suggests; it is in fact a discussion of psychoanalysis in general. In *The Future of an Illusion* (1928) and *Civilization and Its Discontents* (1930) Freud was concerned with the wider application of psychoanalytic knowledge to religion and culture. *The New Introductory Lectures* of 1932 (1933) deal, among other things, with anxiety, dreams, and mental structure. *Analysis Terminable and Interminable* (1937) is concerned with clinical, therapeutic questions. *An Outline of Psychoanalysis* (1938) gives a very succinct, clear account of Freud's final assessment.

In 1954 there was published in English *The Origins of Psychoanalysis* (1950), consisting of a series of letters and scientific drafts written by Freud to the physician Wilhelm Fliess between 1887 and 1902. This is valuable for understanding the evolution of Freud's theory from a neurophysiological to a purely psychological basis.

Progress of the Psychoanalytic Movement.—The steady growth of the movement, despite opposition, was destined to be interrupted in Europe by political events. Hitler's advent to power in Germany led to the virtual suppression of psychoanalysis there and to the emigration of the great majority of German analysts, most of whom ultimately settled in the United States. In 1938 the Nazis seized Austria, and Vienna, the birthplace of psychoanalysis, had to be abandoned, Freud and his family being brought to England by Ernest Jones. Many of the Viennese analysts finally settled in the United States, but some remained in England with Freud and his daughter Anna. Later, the Hungarian society was affected in a similar way. Thus psychoanalytic activity was almost eliminated from central Europe until a gradual reconstruction of work and training became possible after World War II; although other countries, notably the United States and England, gained many workers through immigration. In the United States, moreover, there was a remarkable expansion largely independent of this. The American Psychoanalytic Association numbered fewer than 200 members before the war, but by the

mid-1960s there were about 1,700 members and associates in its various affiliate societies, of whom more than 1,000 were members of the association. The increase was connected with a steady growth in the number and activities of training institutes, a few of which are connected with universities. In the mid-1960s there were 19 training institutes and centres, with about 1,000 students. Psychoanalysis spread rapidly after the war in South America also, especially in Argentina and Brazil. In Great Britain too there was a large increase in membership, from 72 in 1937 to nearly 300 in the 1960s. Other countries with psychoanalytic societies included Canada, Mexico, Austria, Belgium, Denmark, France, Germany, the Netherlands, Italy, Sweden, Switzerland, India, Israel, and Japan. The International Psychoanalytic Association, consisting of these component societies, performed integrating functions. In 1949 it resumed its biennial meetings, interrupted by the war.

During World War II most of the European journals were suppressed or discontinued, but in Great Britain the *International Journal of Psycho-Analysis*, as well as the *British Journal of Medical Psychology*, and in the U.S. the *Psychoanalytic Review* and the *Psychoanalytic Quarterly* continued to appear regularly. After the war some journals, such as the *Revue française de Psychanalyse*, resumed publication, and a number of others appeared for the first time. Such were the Italian *Rivista di Psicoanalisi*, the Argentine *Revista de Psicoanálisis*, the British *Psychoanalytic Study of the Child and Psychoanalysis and the Social Sciences*, and the *Journal of the American Psychoanalytic Association*. The *Year-Book of Psychoanalysis* (reprinted articles) had appeared earlier. In the 1950s the *Annual Survey of Psychoanalysis* (a digest and review) and the *Index of Psychoanalytic Writings* began.

Many of the lines along which further theoretical and technical developments were to occur are implicit in the first part of this article, written by Freud himself. It remains true that patients with the milder neuroses are the most likely to benefit from psychoanalytic therapy. However, the types of patients treated have changed with the years; there are increasing numbers in the categories described by Freud as suffering from malformations of character and sexual inhibitions and abnormalities. Psychoanalytic knowledge has also been applied fruitfully in art and literature (see below), philosophy, and religion.

Psychoanalysis of Children.—Important developments both of theory and technique took shape in this subject, to which Freud's *Analysis of a Phobia in a Five-Year-Old Boy* (1909) was the first contribution. He left its further development to his daughter Anna, whose *Psycho-Analytic Treatment of Children* appeared in German in 1937. Because the child's nature and circumstances differ so much from the adult's, she held that the technique must be modified in important respects. Melanie Klein, working concurrently along different lines, claimed that all the essential principles of psychoanalytic technique could be applied even to very young children, provided that their spontaneous play activities, utterances, and relationship to the analyst be taken as the material for analysis. The ensuing results, both technical and theoretical, led to one of the major psychoanalytic controversies after 1940. Ernest Jones, much impressed by Mrs. Klein's work, had invited her to leave Berlin and settle in London in 1926. There she gained numerous adherents; and the theories and technique deriving from her work developed so rapidly, and their emphasis appeared in some respects so novel, that they began to meet increasing opposition from those who feared that they represented a serious divergence from Freud.

Freud had regarded the Oedipal phase, from about three to five years of age, as of crucial importance in emotional development, and he worked out its psychology with particular thoroughness. On the basis of Freud's findings, two obvious directions of advance were open. One was to study the consolidation of the ego and of its techniques of controlling instinctual impulse, which occurs between the Oedipal phase and the onset of puberty, as well as the transformations of puberty. The other was to work backward chronologically, studying the antecedents of the Oedipus complex; i.e., the pregenital phases, and especially the oral phase, where the mouth is the chief organ for emotionally charged contact, the mother and her breast the most important external object. The

first direction led to very significant contributions to ego psychology, as by Anna Freud; the second led to various results, among which those of Mrs. Klein and her associates were at once outstanding and controversial.

Developments in Theory.—Freud's tripartite division of the mind into id, ego, and superego remained the essential theoretical model, but it became progressively more elaborate. As regards the id, the fundamental importance of aggressive, destructive impulses gained more and more recognition, and Freud's "theoretical speculation" that the two ultimate instinctual forces are those of Eros and destruction became increasingly convincing to him. Freud supposed that aggression originates from a "death instinct"; i.e., an innate tendency to undo the processes leading to life and to revert to the inorganic state from which life originally arose. Manifestly aggressive activity could then be regarded as a partial turning outward of this destructive death impulse, whereby the self is preserved and the aggression used in support of the life instincts, or Eros. Many analysts, although accepting the fundamental importance of the aggressive impulse, have remained unconvinced by Freud's death instinct theory.

The understanding of anxiety and its effects became a central problem, and its control by various devices was recognized as a major function of the ego. It was seen that the most varied human activities, including sexual ones, may sometimes be a means of coping with anxiety rather than a direct outcome of instinctual drives. The effect on theory was a strong stressing of dynamic factors, the topographical schema gradually dropping into a position of relatively less importance. The superego remained an important concept, describing, as it does, a mode of functioning whereby impulses, especially aggressive ones, are redirected toward the self. The intimate connection of guilt feelings with aggressive impulse became clear, and important precursors, or early stages of the superego, related to the pregenital stages of development, were discovered.

The problems of female sexuality received increasing attention, largely on the initiative of certain women analysts, and Freud found it necessary to modify some of his views; e.g., by recognizing the long period of mother-attachment in girls. He was not prepared, however, to abandon his conviction of the fateful consequences of the anatomical sexual difference (see his *New Introductory Lectures*).

Developments in Technique.—These went hand in hand with the changes in theoretical emphasis, and were considerably influenced by the work of child analysts. The full analysis of the patient's behaviour in the analytic situation (the transference) came to be regarded as the most characteristic feature of the psychoanalytic method; the negative or hostile elements in this were recognized as requiring special attention. Much practical importance was attached to the earliest, pregenital stages of personality development. Although the technique of interpretation varied considerably in the hands of different analysts and schools of analysis, the general tendency was in the direction of more active interpretation especially in the sphere of the transference, with emphasis on anxiety, guilt feelings, and defensive maneuvers of the ego.

Developments in Application.—In the clinical field the application of psychoanalysis to children has already been noted. Its application to the treatment of psychoses has followed two main lines. The first is associated with the work of Mrs. Klein, using insights gained from child analysis and from the analysis of early stages of mental development. The second approaches patients from the standpoint of ego psychology, and the failure in psychosis to establish proper ego-boundaries between ego and outer world, etc. Here some kind of reeducation, rather than purely analytic work, is widely considered necessary. The understanding gained from psychoanalytic work has had a profound influence on psychiatry in general, especially in the United States.

Psychoanalytic theory and technique also became applied increasingly to the study of physiology and pathology. These studies of the interrelationship between organic and psychic processes have influenced medical education and the everyday practice of surgery and internal medicine, particularly in the U.S. The study of

crime or delinquency too has been enriched by the application of psychoanalytic experience and theory, especially in England and the U.S. Among many extracurricular applications, that to anthropology and sociology has had striking results in the hands of analytically trained field workers and others, such as Géza Róheim, Margaret Mead, Bronislaw Malinowski, Abram Kardiner, and John Dollard. (W. H. G.)

Areas of Controversy.—Early schisms occurred over such issues as the basic role which Freud ascribed to biological instinctual processes. Jung moved away from this in a direction which was in essence mystical. Otto Rank reverted to an 18th-century facultative will psychology. Alfred Adler placed great emphasis on an artificially isolated power drive. Of necessity these viewpoints entailed a rejection of psychoanalytic technique as well as theory, and the supporters of these psychologies used various names (individual psychology, analytical psychology, etc.) to distinguish their theories from Freud's psychoanalytic psychology.

More recent controversies were over details of Freudian theory or technique and did not lead to a complete departure from the parent stem. The leaders continued to subscribe to the main body of psychoanalytic thought and to look upon themselves as psychoanalysts. Controversies current at mid-20th century focused on such questions as the definition of instincts, details of libido development, and the relative importance of infancy, puberty, and adolescence in the genesis of neurosis; and on such technical issues as the duration and continuity of treatment and the handling of transference phenomena. The controversial issues arising from the work of Melanie Klein (see above) touched on all these matters. A significant area of inquiry was developing around the validity of all quantitative metaphors, as these are used not merely to characterize the interplay of psychological processes but as a basis for explaining variations in human behaviour. This development was related to the rapidly evolving changes in current concepts of the way the human brain works. It was expected that these developments would lead in time to important clarifications and simplifications in the conceptual structure of psychoanalysis. It seemed doubtful that any of the issues in dispute at midcentury would lead to the development of new schools or to such schisms as occurred in earlier years. (L. S. K.; B. D. L.)

INFLUENCE ON ART AND THOUGHT

Psychoanalysis has exerted, from the beginning, a profound influence on literature and the other arts and on the whole body of social thought. Freud and Jung, not only in their broad theoretical works but in their speculations directly upon the nature of art and artist, had the greatest impact. Of Freud's works, the most provocative were *The Interpretation of Dreams* (1900), *Three Contributions to the Theory of Sex* (1905), *Beyond the Pleasure Principle* (1920), and a number of the essays and papers in *The Collected Papers of Sigmund Freud* (the English translation published 1924). Conspicuous for their influence on the arts among these last were such essays as "The Dynamics of the Transference" (vol. ii), "Turnings in the Ways of Psychoanalytic Therapy" (vol. ii), "The Moses of Michelangelo" (vol. iv), "The Relation of the Poet to Day-Dreaming" (vol. iv), and "The Unconscious" (vol. iv). The work of Jung best known to modern writers and artists included *Psychology of the Unconscious* (1916), *Psychological Types, or the Psychology of Individuation* (1920), *Modern Man in Search of a Soul* (1931), and several essays which attempted to explain the psychology of art; of these, his "Psychology and Poetry" (which appeared in *Transition*, translated by Eugene Jolas, in 1930) is perhaps best known.

A number of other pioneers in the establishment of psychoanalysis in the 20th century contributed to the very large body of work on psychology and the arts. Most of these followed up suggestions made originally by Freud and Jung, but they also investigated more exhaustively subjects that were for the most part only peripheral to the major interests of the two leading spokesmen for the field. Among these psychoanalysts who were interested in the application of their disciplines to the arts and to criticism were Wilhelm Stekel, Otto Rank, Ernest Jones, and Charles Baudouin. The most important works of these men were Rank's

The Incest-Motive in Poetry and Legend (1912), Jones's *Hamlet and Oedipus* (1910 and 1949), and Baudouin's *Psychoanalysis and Aesthetics* (1924).

The work of many critics was strongly marked by their preoccupation with psychoanalysis and psychiatry: among them the most influential were Herbert Read, Kenneth Burke, Frederick C. Prescott and Maud Bodkin. Psychoanalytic investigations of the lives of writers and artists were responsible for a large body of additional work. Freud himself contributed to this kind of writing in his *Leonardo da Vinci: a Psychosexual Study of an Infantile Reminiscence* (1910) and in his essay "Dostoyevsky and Parricide" (English translation published in *Partisan Review*, fall, 1945). In both cases, Freud attempted to find in the work of the artists evidence that would help toward an understanding of their "psychic life." Biography, following upon the suggestions contained in these contributions and others, as well as the great body of clinical investigation, developed a special approach toward the arts, in which the work of art was related to and explained in terms of the artist's psychological history. Conspicuous examples of this form of psychobiography were René Laforgue's *The Defeat of Baudelaire: a Psycho-Analytical Study of the Neurosis of Charles Baudelaire* (1931), Saul Rosenzweig's "The Ghost of Henry James" (in *Character and Personality*, Dec. 1943), Edmund Wilson's biographical studies of literature (many of them contained in *The Wound and the Bow*, 1941), Joseph Wood Krutch's *Edgar Allan Poe: a Study in Genius* (1926), and Van Wyck Brooks's biographies of Mark Twain (*The Ordeal of Mark Twain*, 1920) and Henry James (*The Pilgrimage of Henry James*, 1925). Clark Griffith's study of Emily Dickinson (*The Long Shadow*, 1964) exemplified a still more mature use of psychoanalysis in literary biography.

Proponents: Thomas Mann and Others.—The question of the influence—of the degree of it and of all the peculiarities of its nature—is as complex as the influence itself is varied and widespread. There were writers and artists who professed to have and sometimes had a great knowledge of psychoanalysis and who worked in terms of a direct recognition of its value for their art. These included most of the surrealists, some of whom (like André Breton) had had actual experience as analysts, and other writers who (like Ludwig Lewisohn, Georg Groddeck, H. R. Lenormand) spoke of psychoanalysis with varying degrees of accuracy and conviction. Of Lenormand's plays, beginning with *Le Mangeur de Rêves* (1922), those which presented tragedy based chiefly on psychoanalytic knowledge of character included *L'Homme et ses Fantômes* (1924), *Asie* (1931), and *Pacifique* (1937); all these works reflect wide and accurate acquaintance with the discipline and the conclusions of psychoanalysis, though Lenormand objected to their being labeled Freudian.

Also included in this first group of writers was Thomas Mann, who not only knew and greatly respected the work of Freud, but was also extremely judicious in his application of this knowledge to his fiction. In an essay on "Freud's Position in the History of Modern Thought" (1928; included in *Past Masters, and Other Papers*, 1933), Mann applauded Freud for his intelligent concern with the psychic life as well as his wish to find new sources of cure and therapy. One of Mann's first uses of his wide acquaintance with psychoanalysis was in the novel *The Magic Mountain* (1924), but here the reference to psychoanalysis is mixed with a generous and eclectic use of many other kinds of knowledge and speculation—notably the philosophies of Arthur Schopenhauer and Friedrich Nietzsche. That he remained objective concerning the advantages of analysis for modern society was abundantly indicated in such remarks from the novel as this made by the character Settembrini: "Analysis as an instrument of enlightenment and civilization is good, in so far as it shatters absurd convictions, acts as a solvent upon natural prejudices, and undermines authority. . . . But it is bad, . . . in so far as it stands in the way of action, cannot shape the vital forces, maims life at its roots." (*The Magic Mountain*, Thomas Mann, p. 283, Modern Library Edition; A. A. Knopf, Inc., New York, 1927.) In his fictional reconstruction of the biblical story of Joseph, Mann quite deliberately made use of the speculations of both Freud and Jung con-

cerning the value of myth and its symbolic recurrence, through a racial (or "collective") unconscious. Mann's fiction showed the skill of an intellectually disciplined mind whose application of psychoanalysis, as well as of other knowledges, never allowed it to dominate but made it serve the original aesthetic form and subject.

The knowledge of psychoanalysis also led modern novelists to establish the analyst himself as an important fictional personage, sometimes available to satirical observation (as in Waldo Frank's novel *The Bridegroom Cometh*, 1938), sometimes placed in a crucial role as adviser and "physician of the soul" (as in Lewisohn's *The Island Within*, 1928) and sometimes credited with providing the means of a novel's resolution (as in Arthur Koestler's *Arrival and Departure*, 1943). The substance and content of psychoanalytic disclosures (or their equivalents in the artist's imagination) often dominated the content of works of literature. Reliance upon the revelations of the subconscious mind was conspicuous in such works as the fiction of Anaïs Nin; surrealist poetry, prose, and painting; Groddeck's *Der Seelensucher* (1922); F. Scott Fitzgerald's *Tender Is the Night* (1934); Conrad Aiken's *Great Circle* (1933), *King Coffin* (1935), and much of his poetry particularly *The Coming Forth by Day of Osiris Jones*, 1931); and both the poetry and fiction of Dylan Thomas. Notable for its literary approximation of clinical analysis was the novel by Italo Svevo (Ettore Schmitz), *La Coscienza di Zeno* (1924; translated as *The Confessions of Zeno*, 1930), in which the narrative is presented as a continuous self-analysis by the hero. In musical comedy and the theatre the role of the psychoanalyst was presented in Moss Hart's *Lady in the Dark* (1941) and T. S. Eliot's *The Cocktail Party* (1950).

Antagonists and the "Unlabeled": D. H. Lawrence and Others.—A second group of writers and artists included those who undeniably showed the influence of psychoanalysis but who resisted the labels Freudian and psychoanalytic. These persons gained prominence in literature and art in one of two ways: either they formulated their own theories of the unconscious and other psychoanalytic concerns in an effort to disprove Freud or to discount his values; or their work followed the lines and treated of the material with which psychoanalysis was largely concerned without having derived from a study of it. An important opponent of psychoanalysis was D. H. Lawrence; his novel *Sons and Lovers* (1913) interested psychoanalysts and critics who found a direct influence in its presentation of familial problems. Lawrence's reply was to repudiate psychoanalysis as too narrowly and harmfully scientific; but in the energy of his protest lay an earnest of the contribution made by psychoanalysis to his thinking. In a great number of letters and essays, Lawrence attacked both Freud and Jung, though he gave a qualified approval of another analyst, Trigant Burrow. His principal long attacks on psychoanalysis were *Psychoanalysis and the Unconscious* (1921) and *Fantasia of the Unconscious* (1922). In these works, Lawrence accused psychoanalysis of putting a false and debilitating emphasis upon scientific probing and examination which not only misunderstood the vital sources of human action but helped to defeat human vitality and tended to reduce the "life forces" to objects of intellectual curiosity. These reflections were associated in a large portion of Lawrence's writings of every kind with a general attack upon modern rational and intellectual life, as well as with his repudiation of the mechanistic, life-defeating impact of modern industry upon human vitality.

At the same time, a number of other writers offered in their work tempting opportunities for critics who wished directly to attach the label Freudian to them, but in large part rejected it or confessed to an ignorance of the disciplines that had allegedly influenced them. Among these writers were Sherwood Anderson and Eugene O'Neill; particularly in some of the latter's plays especially *Mourning Becomes Electra*, 1931) there is abundant evidence of his realization of psychoanalytic techniques and discoveries, though O'Neill himself denied any direct line of influence. Franz Kafka was a special case: many of his writings show a line of relationship to his own familial circumstances, revealed especially in "Letter to My Father"; but, while critics did quite suc-

cessfully exploit that relationship, Kafka's work derived from a complex of other influences which made a too-simple psychoanalytic explanation misleading. (See *The Kafka Problem*, edited by Angel Flores, 1946.) In the 1950s and 1960s, special approaches to psychoanalysis and to sexual problems achieved prominence among young writers. Wilhelm Reich's books, *The Function of the Orgasm* (1942) and *Character Analysis* (1949), were influential. The problems of the homosexual were explored in several novels, including William Burroughs' *Naked Lunch* (1959) and John Rechy's *The City of Night* (1963).

Psychoanalytic Themes.—Another kind of influence concerned the role of psychoanalysis in some of the major preoccupations of literature. Psychoanalysis could rightfully claim a share in the motivating influence upon the release (of literature chiefly, but of the other arts as well) from the restraining and inhibiting cultural and traditional limits of taste and decorum which had fairly well held until the end of World War I. In these circumstances, psychoanalysis may be considered a social instrument, providing a rationalization of social change; but this was not to be its enduring purpose, nor had it been its original or exclusive aim. In many ways, the conjunction of psychoanalysis with social revolt was accidental, and the notoriety hindered the serious progress of the science as much as it helped to popularize it. The clinical studies begun by Freud and revealed in *Three Contributions to the Theory of Sex* and other places had a rather important voice, though by no means an exclusive one; the work of other psychologists, of sociologists and anthropologists was equally important, and the general impact of the war served as a primary cause of the release of inhibitions among artists regarding the treatment of these matters. What psychoanalysis did was immensely to extend and partly to provide phraseology for the discussion of sex matters or for their dramatization in works of literature. The attitude toward psychoanalysis on this level of influence was often largely undiscriminating, amateurish, and ignorant. The principal terms and the popular notions of psychoanalysis were used over and over again in the popular and semipopular literature of the 1920s, as the Marxist and pseudo-Marxist ideas found their way into the work of the 1930s. The catalogue of works which reflected this type of influence is very great; the use of psychoanalysis was sometimes very shrewd, sometimes quite mistaken and misleading, and often merely the result of a desire to be fashionable. In one way or another the work of the following writers showed the widespread impression made by psychoanalysis upon the modern world: Floyd Dell, Max Eastman, Maxwell Bodenheim, Conrad Aiken, Susan Glaspell, Evelyn Scott, Waldo Frank, F. Scott Fitzgerald, Carl Van Vechten, May Sinclair, J. D. Beresford, and Aldous Huxley. In the work of most of these, psychoanalysis was little more than incidentally acknowledged, or was used merely as a form of intellectual small change. By 1940 the relationship of psychoanalysis to social analysis had become much more complex; it was combined with economic determinations of history, with anthropology, and with theology.

However, it must be stressed that in the first half of the 20th century at least, psychoanalytic influence was often haphazard and incidental, and art borrowed from it a means of confusing its terms and its disciplines. Until the time of World War I, the career of psychoanalysis had been largely handicapped by a considerable rejection of it as a valid psychology. The writer or artist, aware of a significant new contribution to human knowledge, even in the early years, was both distrustful and confused concerning its actual value for him. New terms, discoveries, emphases (or extensions of original terms) served to confuse him further. In addition, the sources of information from which the artist was able to draw were often quite remote in both nature and quality of precision from the original; as psychoanalysis became popular, numerous books, essays, editorials, conversations, and amateurish "games" served often to give portions of "information" or vagrant notions of what psychoanalysis was actually doing. This variety of circumstance accounted for the vast majority of errant and erroneous uses of what was, when separated from its accurate source, mostly a fashionable mode of discourse, or a jargon.

The Unconscious.—Serious and accurate considerations of psychoanalysis led to substantial contributions in at least three separate areas of creative work. The first of these was the study of the unconscious itself—often quite aside from the psychoanalytic purpose for making that study. The pioneering influence in this connection was Freud's *The Interpretation of Dreams*. His investigation of the "dream work" had a profound and widespread effect upon the arts, especially as it gradually made available to artists certain information concerning the "behaviour" of the unconscious. The dream not only provided an extension of the uses to which the various languages of the arts might be put; it also suggested a range and a new reordering of symbolism which could be applied in varied ways to literature and art. In literature, the techniques practised in stream-of-consciousness writing were greatly extended through adaptations or applications of Freud's original suggestions. A considerable range of literary styles was made possible as a consequence, as well as new departures in the structure of novels, plays and poems. The popularity of this method was largely the result of the great success of James Joyce's *Ulysses* (1922), imitated in a great number of novels which followed its publication. *Ulysses* was followed by *Finnegans Wake* (first published in part as "Work in Progress" in the magazine *Transition*, 1927–29; as a book, 1939), a much more elaborate and exhaustive exploitation of the literary resources of psychoanalysis, in combination with many other disciplines, knowledges and techniques available to the erudition of its author. The techniques initiated or perfected by Joyce were subsequently taken in other fictions, stylized, and combined with more traditional forms of analysis. The most important contribution made by them lay in the revisions seen of the individual dream consciousness and a world view that was at once anthropological, mythical, and cultural. Other applications of the information about the unconscious made available to the arts included the so-called automatic writing of the surrealists, especially of André Breton, Louis Aragon, Philippe Soupault, René Crevel, and Paul Éluard. These artists, and others, did not confine themselves, however, to a mere simulation of mental disorders in their work; it did remain close to what the founders of surrealism thought were their psychoanalytic origins. Breton's definition of surrealism, given in the *Manifeste du surréalisme* (1924), established both the nature and the limitation of their work: "Pure psychic automatism by which it is intended to express, verbally, in writing, or by other means, the real process of thought. Thought's dictation, in the absence of all control exercised by the reason and outside all aesthetic and moral preoccupations." (André Breton, *Manifeste du surréalisme*, page 46; Éditions du Sagittaire, Paris, 1924.) In its later development, the sponsors of surrealism acknowledged that such work could easily be confined to a too narrow and repetitious form of creation and proposed (in Breton's essays and in those of Nicholas Calas) to free themselves from the limits of psychoanalytic descriptions of the unconscious. This independence of the limits of clinical psychoanalysis was much less true of surrealist painting (Max Ernst, Yves Tanguy, Salvador Dalí and others), which for the most part continued to realize pictorially and without much variation subjects thought to represent the desires embedded in the unconscious.

Motivations.—The second contribution made by psychoanalysis to modern literature and art had chiefly to do with the reexamination and exposition of human behaviour and the motives underlying it. This revision of view, involving as it did much attention to a person's sex life and his relationship to his parents from infancy on, did much to encourage both illuminating and wildly erroneous changes in the explanation of motive. The range of information concerning such mental disorders as were available, to novelists and dramatists especially, increased as the techniques of psychoanalysis expanded and theorists multiplied. Earlier fiction of the 1920s often remained content to speak superficially of "repressions," "neuroses," and "free association" and to narrate visits to psychoanalysts as part of a social fashion. As familiarity with psychoanalysis increased, the use of it became more "professional" in its efforts to achieve clinical exactness. The novels, dramas, and motion pictures of the late 1930s and thereafter demonstrated

much detailed knowledge of psychiatry and a willingness to exploit its opportunities for characterization and melodrama. An early example of such exploitation is Fitzgerald's *Tender Is the Night* whose major theme depends upon the risk taken by a promising young American psychoanalyst when he marries his patient, and is thus forced to call increasingly upon his reserves of nervous and moral energy until both are completely exhausted. The novel revealed a considerable acquaintance with the terminology, practices, and techniques of the clinic and the sanitarium, and some skill in appropriating them to the problems of a novel's form and structure.

The Mythic Content of Art.—The third contribution is largely the work of Jung. The difference between his influence and Freud's arose chiefly from Jung's explanation of the term "libido." Freud had used this term to designate sexual energy; Jung preferred to expand its definition. Linked with this fundamental difference of interpretation was the much greater emphasis Jung put upon what he called the "collective unconscious," which has been described as "the precipitate of humanity's typical forms of reaction since the earliest beginnings." (J. F. Jacobi, *The Psychology of Jung*, p. 8; Yale University Press, New Haven, Conn., 1943.) The role of the artist became extremely important for Jung; he was considered a form of priest of the "collective unconscious" because he relates the conscious life of his fellows to its archetypes in the unconscious. This view of the unconscious and of its availability to art and literature had no small influence upon 20th-century writers and artists. It was one of several germinal theories which stimulated a great critical interest in myth and mythology. Among the critics whose interpretations of literature showed its influence were Maud Bodkin (*Archetypal Patterns in Poetry*, 1934), Elizabeth Drew (*T. S. Eliot: The Design of His Poetry*, 1949) and P. W. Martin (*Experiment in Depth*, 1955). Jung's influence served in a way to counteract Freud's rather narrow view of the artist and the tendency of his followers to analyze art in terms of the artist's psychic nature. Jung was in a much larger sense concerned with the act of creation and with its significance as a restatement and reshaping of recurrent mythical themes.

At the halfway mark of the 20th century, the usefulness of psychoanalysis for criticism and its influence upon the artist had grown much more complex and varied than at the beginning. New explorations of Freud and Jung continued to appear, as well as a considerable number of studies of the arts by psychoanalysts and by critics of psychoanalysis and psychiatry. In literature especially, the groundwork of psychoanalytic knowledge was accepted as familiar to the majority of both artists and critics.

PSYCHO GALVANIC REFLEX. The term psychogalvanic reflex (PGR) refers to a change in the electrical properties of the body (probably of the skin) following noxious stimulation, stimulation that produces emotional reaction, and, to some extent, stimulation that attracts the subject's attention and leads to an aroused alertness. Galvanic skin response (GSR) and electrodermal response (EDR) are preferable synonyms. Though most of the work on this phenomenon has involved human subjects, it can be demonstrated in other mammals. The PGR can be demonstrated in several ways, but usually with what are essentially modifications and improvements of the method of C. S. Féré (1888).

In these, the response appears as an increase in the electrical conductance of the skin (a decrease in resistance) across the palms of the hands or feet. In the experimental arrangements, the subject forms one arm of a balanced Wheatstone bridge electrical circuit (see INSTRUMENTS, ELECTRICAL MEASURING: *Indicating Instruments*). When his resistance to the passage of a weak, impressed electrical current decreases, the bridge is thrown out of balance, as indicated by the deflection of a galvanometer. The amount of change in his resistance can be calculated from the magnitude of this deflection or from the amount of external resistance that must be introduced elsewhere in the bridge to rebalance it. The response appears with a latency of about two seconds after stimulation with a pinprick, threat of injury, etc.; it rises to a maximum after two to ten seconds and subsides at about the same rate.

The PGR is mediated by the sympathetic division of the auto-

nomic nervous system. It is a part of the general arousal or activation pattern of physiological responses that mobilizes and fits the person for effective reaction in an emergency, as described by Cannon (1932). In addition, parts of the premotor cerebral cortex appear to have a role in producing the PGR, and Darrow (1936) suggested that it is an accessory to the activity of the postural mechanisms, for which it could play a preparatory function. The consensus is that the PGR is associated with activation of the sweat glands by the postganglionic sympathetic fibres, but that the perspiration actually secreted does not produce the characteristic decrease in skin resistance by acting as an electrolytic conductor.

A more sensitive indicator of minimal emotional arousal than other physiological responses, the PGR has figured extensively in studies of emotion and emotional learning. It can help to uncover complexes of emotional sensitivities when used with word association tests or interviews; by observing when the response occurs, the skilled worker can deduce which stimuli evoke emotional disturbance. The PGR is involuntary in the sense that subjects cannot suppress it readily, if at all, though it can be produced by voluntary acts such as deep breathing or moving. As a detector of emotion, the response often has served as one of the indicators in the "lie detector," along with blood pressure, pulse, and respiration. If a neutral stimulus such as a light or tone is paired with mild pain, the neutral stimulus acquires the power to evoke the PGR. With such conditioning, the response can become a useful indicator for studying human learning as well as for detecting feigned deafness, blindness, or anesthesia. See also EMOTION.

PSYCHOLOGICAL TESTS AND MEASUREMENTS.

A psychological test may be defined as a scientifically standardized procedure for assessing some clearly defined mental characteristic. It is the empirical standardization—particularly the preliminary checking and calibration by *ad hoc* research—that distinguishes a psychological test from an ordinary interview or a typical academic examination.

This article is organized as follows:

I. Historical Development

1. Earliest Types of Test
2. General and Special Abilities
3. Group Tests
4. Performance Tests
5. Vocational Testing
6. Testing Temperamental Characteristics
7. Recent Research

II. Characteristics Measured, Construction and Uses

- A. Characteristics Measured
 1. Educational and Vocational Attainments
 2. General and Special Abilities
- B. Construction and Standardization
 1. Sampling of Tests and Persons
 2. Reliability
 3. Validity
 4. Types of Measurement
 5. Comparable Scales
- C. Uses of Psychological Tests
 1. Theoretical Value
 2. Practical Value

III. Tests of Personality and Temperament

- A. Early Tests of Personality
 1. Free Association
 2. Questionnaire
 3. Ink Blot
 4. Situational-Observational
- B. Objective or Structured Tests
 1. SVIB
 2. Kuder Preference Record
 3. Minnesota Multiphasic
- C. Study of Values
- D. Factor Analysis
- E. Projective Methods
 1. Theory of Projective Methods
 2. Rorschach Test
 3. Thematic Apperception Test

F. Other Methods

1. Constitutive Methods
2. Constructive Methods
3. Interpretive Methods
4. Cathartic Methods
5. Refractive Methods

IV. Attitude Measurement

A. Approaches

1. Methods Focusing on Statements
2. Method Focusing on Subjects
3. Methods Focusing on Responses
4. Internal Consistency, Reliability, and Validity

B. Consumer Preference Measurement

1. Multidimensional Scaling
2. Detection of Sensory Differences in Consumer Products

I. HISTORICAL DEVELOPMENT

1. Earliest Types of Test.—The need for precise techniques to assess mental differences between individuals was first explicitly recognized by Sir Francis Galton (*q.v.*) and formed an essential part of his attempt to transform individual psychology into a genuine science. During the latter half of the 19th century, when psychology was becoming an experimental science, it was found that laboratory measurements displayed marked variations from one person to another. Interest at that time centred chiefly on the general study of conscious activities as such, and these individual variations were consequently treated as errors of measurement, to be eliminated by some method of averaging. Galton noted that many of the differences seemed to be related to the individual's ability and temperamental characteristics as displayed in everyday life, and resolved to study and standardize the procedures from this new point of view.

Of his earlier "mental tests" (as he called them), many were suggested by the experimental techniques already used in laboratory work. In Great Britain the dominant school of psychology at that date held that all conscious processes developed out of the sensory experiences of the individual or the associations formed between them. It seemed to follow that a subject's general efficiency might best be measured by testing his ability to discriminate elementary stimuli. Galton therefore began by devising methods for measuring tactile, visual, auditory, and muscular discrimination. The discrimination of weights had long been employed by E. H. Weber, G. Fechner (*qq.v.*) and their followers to demonstrate the general Weber-Fechner law (*see* PSYCHOPHYSICAL METHODS) and one of Galton's earliest and best-known tests consisted of a calibrated series of weights for measuring the accuracy with which each person could discriminate such differences. These sensory tests were later supplemented by tests for speed and strength of movement, quickness of reaction, and extent of associative memory. Later Galton came to realize that still more complex processes would yield better estimates of general efficiency and accordingly constructed a number of tests for "higher mental processes." No less valuable were the statistical techniques that he devised for validating and standardizing the new procedures—the percentile and the average deviation as metrical units, the scaling methods based on the normal frequency distribution, and above all the coefficient of correlation (*see* STATISTICS).

In the later stages of his work he received active assistance from J. M. Cattell (*q.v.*), a U.S. student who had worked in Wilhelm Wundt's laboratory at Leipzig and acted for a short time as Galton's assistant. In 1890 Galton and Cattell published the program of those tests which, with various other devices, Galton had regularly used in his anthropometric laboratory for studying the characteristics of individuals. On returning to the United States, Cattell and his co-workers started at Columbia University the systematic application of a similar scheme of tests to college students and thus initiated the long series of researches carried out with the aid of these new techniques. The most important was embodied in a large and influential monograph (1901) by C. Wissler (one of Cattell's research students), which reviewed the results obtained and applied for the first time the Galton-Pearson correlation coefficient to measure the relations of the test results with each other and with independent criteria; the correlations of the tests with such criteria as academic performance were disappointingly low.

In 1892 James Sully had opened a department of education at

University College, London, where a school for boys happened to be available on the premises. There he and Galton (who had transferred his laboratory to the college) joined in applying tests of physical and mental characteristics to schoolchildren. Sully held that the measurement of attention would provide the best estimates of a child's intelligence; accordingly he devised tests for the "span of prehension" (the maximum number of letters comprehended in a single glance or of digits recalled after a single hearing) and claimed that the differences thus detected varied closely with the child's "general mental capacity."

In 1902 Galton obtained a grant from the British Association for the Advancement of Science for repeating his anthropometric survey of the British Isles, with the inclusion of tests for mental capacities, and a committee was formed to make preliminary inquiries with W. McDougall (head of Sully's laboratory in London) as secretary. It worked in cooperation with a second committee appointed to study psychophysiological factors in education. The outcome was a series of investigations, carried out mainly under McDougall's guidance, by W. Brown, C. Burt, C. Spearman, and others, with a view to constructing intelligence tests for schoolchildren.

2. General and Special Abilities.—Galton, in the course of his investigations, had been led to distinguish between "special aptitudes" (corresponding roughly to the old-fashioned "faculties") and "general ability"—a kind of superfaculty determining mental efficiency in all forms of cognitive activity. In France Alfred Binet (*q.v.*), an admirer of contemporary British psychology and particularly of the views elaborated by Galton, adopted this distinction, but since in French the word "ability" possessed a different meaning he substituted Herbert Spencer's term "intelligence." In 1904 the French ministry of public instruction appointed a commission to study the diagnosis and training of mentally deficient children; and, as a member of the commission, Binet set about compiling standardized scales for measuring not only "pedagogical attainments" but also what he termed "general intelligence" and "partial aptitudes." He determined to discard "the instrumental methods popular in German laboratories" and to compile a series of problems, graded in difficulty and requiring for their solution "little else but pencil, paper, pictures, and a few common objects." The success of his novel procedure as a means of diagnosing subnormal pupils attracted widespread attention, and his age scale of intelligence tests was almost immediately translated and adapted by psychologists in Belgium, Britain, Germany, and the U.S.

3. Group Tests.—All these earlier tests had to be applied individually. For the purpose of large-scale examinations of schoolchildren, however, it was desirable if possible to develop a type of test which could be applied collectively. Accordingly, in London and elsewhere a number of researches were carried out to investigate the possible use of what were subsequently known as group tests. The result was the type of problem commonly used in the so-called 11+ examination, an academic placement instrument administered to English children at about age 11: "analogies," "opposites," "syllogistic reasoning," "code tests," "completion tests" (a device suggested by H. Ebbinghaus) and the like, usually combined into a booklet of half a dozen subtests. Similar principles were adopted for constructing and standardizing tests for the chief subjects of the school curriculum, and in 1913 the London County Council appointed an official psychologist to study and apply such tests, particularly in connection with the examination of children of subnormal and supernormal ability.

4. Performance Tests.—In the United States, in order to test foreign immigrants, special attention was given to performance tests; *i.e.*, tests not entailing a knowledge of some particular language. H. A. Knox developed "construction" and "imitation" tests. S. D. Porteus a series of graded maze tests, H. H. Goddard and W. F. Dearborn form boards, W. Healy a picture-completion test. Finally, R. Pintner and D. G. Paterson combined a carefully chosen selection to form a "performance scale" which was widely used for those handicapped by deafness, lack of schooling, or other disabilities. In the field of education E. L. Thorndike (*q.v.*), who had joined Cattell at Columbia, quickly became the leader of the test movement in the United States and, though at first doubtful about

the hypothesis of a general ability, was active in producing scientifically standardized tests of scholastic abilities. By the end of the first decade of the 20th century more than 50 well-tried tests for various abilities—sensory discrimination, perception, memory, attention, learning, imagination and the like—were available in standard form and were described in G. M. Whipple's *Manual of Mental and Physical Tests* (1910), with tabulated norms of performances and full instructions for use.

5. Vocational Testing.—Just before the outbreak of World War I, Hugo Münsterberg (*q.v.*) and others in the United States initiated a series of pioneer investigations on adolescents and adults to study the value of psychological tests for purposes of vocational guidance and selection (*see* PSYCHOLOGY, APPLIED). During the war group tests of intelligence were administered to about 1,750,000 recruits for the U.S. Army, and a more limited use was made of aptitude tests for assigning men and women to the most suitable trades in the various fighting services. Similar efforts on a more restricted scale were made in Great Britain. The success of such methods for military purposes resulted after the war in a rapid development of psychological testing for educational and industrial purposes. The experience gained in these two fields during the 20 years of peace proved invaluable in World War II, when both countries made full use of such testing in the various branches of their armed forces.

6. Testing Temperamental Characteristics.—The application of test procedures to what were called affective and conative (as distinct from cognitive) aspects of behaviour developed far more slowly. The emphasis laid by McDougall on emotional tendencies as being the chief determinants of personality and character led several of his research students to apply test procedures to the assessment of temperamental qualities. At first the procedures used were based chiefly on the ordinary laboratory techniques for investigating the physical effects of emotion—changes in blood pressure, the pulse rate, skin temperature, and, most striking of all, the so-called psychogalvanic reflex (a transitory increase in the electrical conductivity of the skin induced by emotional experience). As with intellectual testing, it soon appeared that tests based on these more elementary processes and requiring highly elaborate apparatus were neither the most convenient nor the most effective. Galton had already attempted "psychometric experiments" for the study of associated ideas and had inferred that such devices revealed unconscious interests and motives, particularly early sentiments strongly tinged with emotion, differing widely with different individuals. For stimuli he relied mainly on emotionally suggestive words. Later investigators tried pictures, ink blots (first used by Binet), or ambiguous drawings (a method described by William James) and so developed what British psychologists called apperception tests and U.S. writers call projective tests. The popularization of these procedures and the growing interest in the affective aspects of behaviour (due largely to the influence of the psychoanalytic school) led to numerous researches in the hope of assessing these more hidden constituents of personality.

7. Recent Research.—From about 1930 onward there were no new developments affecting the basic principles or ideas, most of the work being concerned either with improving research techniques already introduced or with devising and applying tests for an ever widening range of abilities, attainments, and other characteristics of individual behaviour. On the theoretical side special attention was paid to the refinement of the statistical procedures used in constructing and evaluating new test batteries, and particularly to such technical questions as scaling, reliability, item analysis, factor analysis, better sampling of test items and test populations and, above all, to improved criteria for validation. On the practical side, the increasing use of tests for educational, commercial, and military purposes, especially by public bodies, led to an attempt to assess not merely theoretical value but also the practical value of large-scale testing: test B may have a much lower theoretical validity than test A and yet, because it adds more to information already available and is at the same time far less expensive, it may have a much higher practical value for the purpose intended. Since financial considerations

are involved, it is desirable to measure the utility of a test by applying the mathematical procedures used in what the economist terms decision theory.

A classified list of tests available for various purposes, with a detailed description and critical evaluation of each, is to be found in the *Mental Measurements Yearbook*, published about every five years by Oscar Buros. The *Sixth Mental Measurements Yearbook* (1965) reported that there were in print 2,171 different tests; the majority are achievement tests, dealing with the chief subjects of the school, college, and university curricula. In these important fields the U.S. Educational Testing Service and College Entrance Examination Board have been particularly active in the 1960s. In Britain similar researches on a far more limited scale have been undertaken by the National Foundation for Educational Research.

Most psychological tests are comparatively short-lived and are quickly replaced in the same way that fashions come and go in women's clothing. A few, however, have proved to be relatively enduring. Of these the best known is the original Binet scale; in Britain one of the London revisions and in the U.S. one of the Terman revisions (the Stanford-Binet) were in regular use in the 1960s, particularly for individual examination of educationally subnormal children. A late version of the latter exists in two forms and contains 62 items grouped into levels of difficulty corresponding to each successive year from infancy to maturity; *e.g.*, for age 5 typical tasks include: defining words by classification or description (two easy words from a standard list of 45), copying a square, repeating a sentence of five monosyllables from memory; for year 10, reading and summarizing a short paragraph, indicating what is absurd in a picture, repeating six digits. For testing adults the Wechsler-Bellevue intelligence scale gained widespread popularity during the 1950s, particularly with clinicians; by the 1960s it was being largely replaced in the U.S. by the Wechsler Adult Intelligence Scale (WAIS). This consists of verbal and performance tests, and, with the aid of a conversion table, the measurements are expressed in terms of a conventional intelligence quotient; a lower-level version (the Wechsler Intelligence Scale for Children: WISC) also was devised for use with children. Other tests are available for infants, for the blind, the deaf, and those otherwise handicapped.

Group tests of intelligence are even more widely used. Under this title the *Yearbook* describes more than 100 U.S. versions, available to the general public, most of them composite instruments based on about half a dozen of the stock types of problem described above. In Britain fresh group tests are prepared every year, but are not published until they are no longer required for official purposes. The name intelligence test is perhaps misleading; most of them are not so much tests of innate general ability as tests for general classification.

Less progress has been made with individual tests for special kinds of ability—observation, memory, imagery, creativity, and the like; but improved apparatus is continually being devised for measuring sensory functions—visual acuity, colour vision, hearing, and so on. So-called multiaptitude batteries have become increasingly popular; these commonly cover such aptitudes as verbal, numerical, and mechanical abilities and, less frequently, speed, accuracy, memory, judgment, reasoning, etc. One of the earliest and best known is L. L. Thurstone's test of primary mental abilities, which largely provided a model for later batteries of this type. There are in addition numerous tests for more complex abilities; *e.g.*, artistic and musical aptitudes, and aptitudes for medicine, law, engineering, teaching, and the clerical professions.

II. CHARACTERISTICS MEASURED, CONSTRUCTION AND USES

A. CHARACTERISTICS MEASURED

As a result of a vast amount of detailed research on the lines of these earlier inquiries, three main types of characteristic can now be measured by means of psychological tests or similar devices with tolerable accuracy. The majority of the tests in regular use can be accordingly classified under three main heads: (1)

tests of attainments (*i.e.*, of achievement: knowledge or skill in various fields); (2) tests of abilities, either intellectual or practical; and (3) tests of other characteristics of personality; *e.g.*, emotional, temperamental, and moral qualities (including interests, attitudes, ideals, and motivational tendencies generally).

1. Educational and Vocational Attainments.—The attainments commonly tested may be subdivided into two broad groups, educational and vocational. Of the educational or scholastic tests the most thoroughly standardized are those designed to measure achievement in the ordinary subjects of the elementary school curriculum—reading, spelling, arithmetic, composition, drawing, handwriting, and handwork. With these the norms usually consist of standard (*i.e.*, average) performances for each sex separately at different ages of school life, together with some indication of the range of individual variation (generally in the form of standard deviations) and of border lines for certain types of child or school; *e.g.*, for mentally deficient children or special schools for the educationally subnormal.

Tests also are available for more advanced subjects in the curriculum, to be used with older children at the secondary school stage; *e.g.*, for foreign languages, both ancient and modern, and for the various branches of mathematics and science. However, because of the difficulty of securing fair samples of pupils at the higher stages, the standardization of such tests is less reliable. Attempts have also been made, particularly in the United States, to develop tests for academic subjects taken at the university—teaching, medicine, dentistry, engineering, accounting, languages, and law.

For occupational guidance and for selection in commerce and industry, vocational psychologists endeavoured to construct tests for assessing the extent to which a given applicant possesses the kinds of knowledge and skill required for this or that specific type of employment. Norms of performance are commonly given for the occupations to which they relate and border lines below which efficient performance is relatively unlikely. Many large firms maintain their own trade-test departments for compiling, standardizing, and administering tests of the proficiency of their own employees.

2. General and Special Abilities.—Tests of ability differ from tests of attainment or achievement in that, while the latter are intended to measure the actual results derived by formal education or occupational training, the former seek to estimate differences in so-called mental ability, regardless of the effects of instruction, training, or experience.

Galton's contention that there were two main types of cognitive function for which tests could be developed—general ability and special aptitudes—met with a double opposition. Spearman and his followers contended that the assumption of a single general factor only would suffice to account for all innate intellectual differences; the hypothesis of special abilities or aptitudes they repudiated as an obsolete relic of the old-fashioned theory of faculties. On the other hand, most U.S. investigators—Thorndike, Thurstone, and their collaborators—accepted the existence of special or primary abilities but were highly skeptical of anything described as general ability or "intelligence." The numerous researches carried out by educational and industrial psychologists leave little doubt about the existence of special abilities, and in his later years even Spearman acknowledged their influence, at least on a limited scale. Most British psychologists accept the hypothesis of general intelligence as well, and the majority of the former critics—Thorndike, Brown, Godfrey Thomson, and Thurstone—retracted or at any rate moderated their earlier objections in varying degrees.

The attempt to identify the precise nature of the various special abilities or aptitudes has formed an important object of later factorial research. Unlike the "faculties" of the older psychologists, the abilities that can most readily be distinguished turn out to be decidedly complex and may themselves be analyzed or subdivided into more elementary types of ability, almost without limit. In fact, there seems to be a hierarchy of abilities: the more general are usually the earliest to mature; but during the course of the child's development, they become progressively differentiated into

the more specialized, while the more elementary tend to combine into the more complex.

The special abilities so far established may be conveniently classified according as they arise from differences in the processes involved or in terms of their content. The latter are the easiest to isolate and measure. The more elementary relate to differences in the sensory content: effective tests are available for the visual perception of form and colour, for the discrimination of audible pitch and loudness, and for the discrimination of touch, weight, and muscular movement. Equally well established are the differences between the chief types of conscious imagery, and there are tests and questionnaires intended to discriminate between visualizers, audiles, motiles, and (most common) the various mixtures. From the standpoint of educational and vocational guidance, four content factors are of prime importance, namely, the abilities (or groups of abilities) which underlie (1) the understanding and the use of words (so-called verbal ability), (2) the understanding and use of number and numerical relations (so-called arithmetical ability), (3) the visual and kinesthetic perception of space and (4) the control of coordinated movements such as are involved in mechanical dexterity. Less clearly distinguishable are the factors entering into the understanding and use of relations, especially logical relations, and into aesthetic appreciation in its various forms.

Of factors defined in terms of the processes involved, the most important are those for speed, mechanical memory, productive association (*i.e.*, imagination or, as it is now termed, "creativity"), and certain formal processes underlying rational thinking—abstraction, generalization, and inductive and deductive inference. Since efficiency in tests for all these different activities depends in some degree on general ability or "intelligence," it is essential, when assessing the primary or specific ability in and for itself, to include some test of intelligence as well in order to eliminate its effects by such statistical techniques as partial correlation. On the whole, however, it must be admitted that tests for special abilities can claim neither the high reliability nor the relatively high validity of tests for general intelligence.

With young children it is desirable, as far as possible, to assess innate potentialities—a problem which cannot be solved by tests alone. With adults it is usually sufficient to assess their actual abilities or aptitudes at the time of testing. Accordingly, the earliest vocational tests were commonly based not so much on abstract psychological theory as on a direct study of the work required, often investigated at first hand by a psychologist who himself undertook employment on the job in question. However, the attempt to compile efficient tests for the complex aptitudes required in all the various branches of commerce or industry is a lengthy and circuitous way of tackling the problem. Hence experts in vocational guidance tended more and more to determine the fundamental abilities required for different occupations on the assumption that the same elementary ability may enter (though in varying degrees) into several different occupations. For this purpose the results of theoretical studies, particularly by factorial techniques, have proved of increasing value.

Before turning to the method of assessing temperamental characteristics and what is commonly termed personality, it will be well to consider first of all the various technical devices that were progressively worked out for compiling and calibrating tests of abilities and attainment and then to review the chief uses, both theoretical and practical, to which such tests may be put.

B. CONSTRUCTION AND STANDARDIZATION

1. Sampling of Tests and Persons.—Since psychological measurements are far more liable to be affected by error than bodily or physical measurements, special care has been devoted to ascertaining the most effective methods for constructing and calibrating the procedures used. The first requisite is to define, in precise scientific language and in the light of current psychological theory, the particular characteristic to be measured. Such a definition is needed not merely to select suitable tasks or test material but also to secure an adequate criterion. The abstract definition must be capable of translation into concrete operational terms, so as to indicate what will be the outward and visible signs

of the inner postulated trait. The kind of behaviour chosen for observation may consist of answers to oral or printed questions, manipulations of the parts of some piece of apparatus, or relatively complex reactions to some standard situation.

The main part of the psychologist's task, however, is to test the test; *i.e.*, to determine (1) its reliability and (2) its validity. This involves a twofold process of sampling: it is essential (a) that the items selected for the test include typical specimens of the activities in question and (b) that the persons selected for testing form a typical sample of the population for whom the test is designed. Both items and persons therefore must be chosen to ensure that the samples are genuinely random or at any rate truly representative. As a rule in the trial experiment the number of persons tested will be far smaller than the number to whom the test eventually is to be applied. On the other hand, the number of items should be much larger than the number to be incorporated in the final version. The items selected must be as numerous and as varied as the conditions of the examination permit. Consequently, unlike the question paper set at an ordinary examination which usually requires one full-length essay or about four to eight questions involving fairly long replies, most psychological tests comprise a large number of short problems—often as many as 50 or more to be answered in half an hour. Each is so framed as to reduce to a minimum all irrelevant forms of skill and knowledge (*e.g.*, reading, writing, and cultural information) and to elicit answers that require a minimum of subjective judgment in deciding whether each reply is right or wrong. For example, "Jim is taller than Harry, but shorter than Tom; and Dick is shorter than Harry: which is the tallest of the four—Jim, Tom, Dick, or Harry? (put a line under the right name)." In such a question all the words used can be read by an average child of seven, but the problem in reasoning cannot be solved until a mental age of nearly ten, when practically every child, dull or bright, can read the sentence. For such children, therefore, the ability to find the correct answer depends almost entirely on their ability to reason, and their replies can be marked mechanically by a clerk or even a machine.

2. Reliability.—In administering the preliminary version the first thing is to ascertain whether the results are self-consistent or, as it is usually termed, reliable. When any object or quality is measured more than once, the measurements almost invariably differ in some degree, and with psychological traits the variations may be fairly large. Hence earlier investigators made a practice of applying each test at least twice and calculating the correlation between the two sets of results. Later investigators were more often content with a single application and divided the entire series of items into two equivalent subsections. In this case one procedure is to carry out what is tantamount to calculating the correlation between the two subsections. The correlation computed by one or the other of these methods is known as the reliability coefficient. However, it must be understood that "reliability" estimated from only one administration of a test does not indicate consistency from time to time, and is to be regarded only as a measure of internal consistency.

3. Validity.—The validity of a test is commonly defined as the degree to which it succeeds in measuring the trait that it was intended to measure. For this a criterion is needed. The simplest check is to obtain subjective estimates for the trait drawn up by one or more experienced observers who have known the persons tested for a long period. When the test is to be used as a predictor, it is better to follow up the persons tested during subsequent years and secure new and independent measurements based on their after histories. Occasionally some well-established test of high reliability and validity is deemed a sufficient criterion. In all these cases the validity of the new test is assessed by correlating the test results with those of the criterion, and the index thus obtained is known as the validity coefficient. But, where practicable, by far the safest procedure is to base the criterion not on a single set of assessments derived from direct observation or on a single test but on a wide range of tests and assessments, all assumed to measure the same quality; the criterion will then be the general factor underlying the whole series of assessments, each being duly

weighted. This method involves calibration by means of factor analysis (*see below*). With a composite test, it is also desirable to validate not merely the test as a whole but each component item—a procedure known as item analysis—and those items that show the lowest correlations with the criterion are then eliminated.

4. Types of Measurement.—When an acceptably reliable and valid version has at length been constructed, the final step is to reduce the assessments to terms of a quantitative scale and then compile norms for precisely defined groups of the general population; *e.g.*, in the case of children, average performances for either sex at each successive age. To obtain scaled assessments for different kinds of trait, various types of measurement are available; *e.g.*, (1) classificatory, requiring only the determination of the presence or absence of the class attribute, expressed on a binary scale by 0 or 1; (2) ranking, requiring the determination of more or less, expressed by ordinal numbers; (3) differential, requiring the determination of equal differences or intervals; (4) ratio scales, requiring the determination of equality of ratio; (5) multidimensional scales, expressed by the assignment of a matrix of numbers.

In some instances, as in testing for colour blindness, the assessment is essentially qualitative or classificatory. Modern psychology, however, is skeptical of classification into types: borderline cases and mixed types are nearly always found and are often the most numerous. As a rule, therefore, the assessment is quantitative, and the ultimate aim is to obtain a graded measurement. With many tests (*e.g.*, for drawing or handwriting) the quality assessed exhibits varying degrees of excellence, and these have to be judged by subjective impression. In such a case the nearest approach to a comparable measurement is obtained by simply arranging the individual's performances in an order of merit. Each examinee is then given a rank, stating his position in the whole group, but, since groups differ in size, the ranks are converted to percentile form (*see PERCENTAGE*). However, the intervals between successive ranks and percentiles are far from equal, since persons near the general average are usually far more numerous than those toward either extreme. Hence neither ranks nor percentiles are additive. With the majority of tests it is reasonable to assume that, in a representative sample of the population, the underlying measurements will be distributed approximately in accordance with the normal curve. Accordingly, by using tables for the normal distribution, any percentile can be converted into a multiple of the standard deviation (*s.d.*). Such measurements are said to be in standard measure or standard score (*see below*).

Often, however, the trait itself by its very nature implies an appropriate quantitative measure. With tests for elementary processes, such as sensory discrimination or speed of reaction, for instance, there are as a rule obvious objective units; *e.g.*, grams for the discrimination of weight, seconds for the measurement of speed. As ordinarily administered, many of the tests for higher mental processes also turn, directly or indirectly, on the measurement of speed. With group tests a limited time is usually imposed, and the raw measurement consists of the number of correct solutions achieved in the time allowed. With individual tests a limited number of problems may be set, each of similar difficulty as the others and all well within the capacity of the examinees; the measurement then consists of the time taken by the person to complete them all. Speed, however, is not always a satisfactory index of ability, and in general it is better to use a series of items, varying in difficulty and arranged in order of increasing complexity, from one so easy that almost all can answer it up to one so hard that almost all will fail; with this modification the actual number correctly solved really depends more on qualitative efficiency than on sheer speed. Tests of the former type are termed uniform tests and tests of the latter type graded tests.

5. Comparable Scales.—*Standard Measure.*—With such varying procedures and different methods of construction the raw measurements, taken as they stand, will seldom be comparable from one test to another. Hence it is usually desirable to convert the measurements as originally obtained to terms of a scale where the

zero point and the unit shall always indicate the same amounts. This means a further process of calibration. One device, which is almost always available in a well-planned research, is to treat the average of the entire sample of persons as marking the zero point for the general population; different individuals can then be measured in terms of their deviation about this average, and each deviation can be expressed as a multiple of the standard deviation of the group. Once again, then, the measurements will be in "standard measure." Yet, even here, it is often wiser to deduce each standardized measurement indirectly from the examinee's rank (as described above) instead of directly from the raw measurements themselves. Measurements in terms of the s.d. involve the use of plus and minus signs and of fractions—a type of scaling which has obvious inconveniences in actual practice. Consequently, it is often preferable to substitute an artificial scale in which all the measurements are positive integers—e.g., one with a mean of 50 and an s.d. of 10, or a mean of 100 and an s.d. of 15; the latter has the additional merit of yielding scores that resemble the familiar intelligence quotients.

Intelligence Quotients.—As originally computed the intelligence quotient or mental ratio developed out of a method of standardization popularized by Binet. For the fundamental unit he proposed to take the increment of growth from year to year, with the ability of a newborn infant as the zero point. On this basis characteristics which, like intelligence, mature with increasing age or, like school attainments, accumulate from year to year can be assessed in terms of a mental age. Binet therefore standardized the various problems in his scale according to the age at which the typical child could correctly answer them, the whole series thus forming an age scale measuring intelligence in terms of mental years.

However, unless the children to be compared are all of the same chronological age, this does not yield a satisfactory indication of their basic ability. With many graded tests, including Binet's, the standard deviation for successive age groups increases roughly in proportion to the increase in age. This suggests using the ratio of the child's mental age to his chronological age (usually expressed in percentage form) as an index which may be expected to preserve a fair degree of constancy from year to year up to the time of puberty—a device first proposed by Wilhelm Stern in 1911. With a percentage scale the mean is necessarily 100 and, with the versions of the Binet intelligence scale commonly used in the U.S. and Britain, the standard deviation for complete age groups is approximately 15. However, the underlying assumptions on which the method is based are only broadly true, and "mental ages" and "mental ratios" or "quotients" computed in this way are suited only for rough practical purposes, not for scientific research. In the vast majority of cases the most satisfactory scale is one based on standard measures derived from percentile ranks.

Other methods of scaling, based on more complicated statistical techniques, were put forward from time to time, some of them intended to provide an "absolute scale." Since tested characteristics often consist of patterns of traits rather than of simple graded qualities, one or two statistical writers suggested that the ideal measurement in psychology should take the form not of a single figure but of a "matrix" of elementary assessments, such as will describe a complex structure rather than an isolated tendency and can itself be treated as a unitary system. The easiest way to handle such a matrix is to convert it by statistical transformation into a "factor"—a method developed by British psychologists who adopted Karl Pearson's techniques.

C. USES OF PSYCHOLOGICAL TESTS

1. Theoretical Value.—Psychological tests are widely used both as a research technique for investigating the basic characteristics of human functions and as a practical tool in studying individuals for purposes of educational or vocational guidance. Their adoption for such purposes, however, has not escaped criticism, particularly from psychologists of the Cambridge school such as C. S. Myers and O. L. Zangwill. That their warnings need to be borne in mind is shown by the exaggerated claims of validity often made and by the way in which teachers, school

doctors, and some psychologists and education authorities rely on standardized tests as if they could always be accepted at face value. Nevertheless, such methods can be helpful in the hands of those who have been adequately trained in their use and are aware of their inevitable and substantial limitations.

Contrary to the common notion, such tests were first devised for the solution of theoretical rather than practical problems. Galton and most of his immediate followers were interested primarily in the inheritance of intelligence. To some extent their early inferences were vitiated by the naïve assumption that hereditary characteristics are directly measurable. As far as human beings are concerned, any actual measurement is the product of heredity and environment interacting and, without special mathematical techniques, it is difficult to disentangle their relative influence. However, in spite of persistent skepticism as to the possibility of distinguishing the two components, there has been a fruitful revival of research in psychogenetics, and the substitution of R. A. Fisher's statistical procedures for the cruder methods of Galton and Pearson has yielded trustworthy conclusions in regard to the inheritance of intelligence and other psychological characteristics.

The interest of McDougall and those who worked with him centred rather on what they called the structure of the mind. McDougall himself conceived of hypothetical abilities and emotional propensities as analogous to the hypothetical "forces" of physics. This analogy suggested the adoption of a mode of analysis that would resolve the more complex manifestations of behaviour (the "resultants" of such forces) into elementary "components" in accordance with the so-called parallelogram law of mechanics (*q.v.*). For this purpose Pearson's mathematical formulas for reducing a matrix of correlation coefficients to a set of uncorrelated components seemed to provide the most appropriate working procedure, and, in various simplified forms, it was widely used for determining the "factors of the mind" both on the cognitive (or intellectual) and on the affective and conative (*i.e.*, motivational) aspects. Tests are then constructed for estimating the various "general" and "special" factors; e.g., general intelligence and special or primary abilities on the cognitive side. Here again criticism was active, being directed partly against the type of personality structure conceived by different investigators and partly against the somewhat crude computing methods used by earlier workers. The introduction of electronic means of calculation have made it practicable to adopt more precise and elaborate techniques, which have led to improvements in the test procedures themselves and in the assumptions on which they are based.

2. Practical Value.—From 1910 onward the rapid developments of psychological testing was due to the recognition of its many practical uses. In Britain, particularly in large industrial areas such as London and Liverpool, with their overcrowded slums, the poverty, squalor, and truancy, together with the hostility of many parents to the aims of the schools, prevented many pupils from achieving the full educational progress of which they were in fact capable. Surveys carried out during the earlier decades of the 20th century showed that many children were being certified as mentally deficient who were merely dull or backward, while many who had high ability failed to pass the scholarship examination which entitled them to a free place in a secondary school. The introduction of intelligence tests together with other psychological techniques did much to alleviate these forms of educational injustice.

Where tests are used for selection on an extensive scale, their predictive value is commonly assessed in terms of a correlation coefficient. Thus, to check the efficiency of the so-called 11+ examination carried out annually by most English education authorities (when about 700,000 pupils are examined for admission to a grammar school), representative samples are followed up and reports obtained from the headmasters toward the end of the secondary course. On an average about 20% are selected from the entire age group, and roughly one-fourth of those selected are subsequently reported as unsuitable, while about the same number of those rejected appear to have been rejected wrongly. These

proportions are equivalent to a correlation coefficient of nearly .90. The apparent errors have led to complaints that this method of selection is unfair. In defense of the system, however, it has been stated that the pupils who are wrongly selected or wrongly rejected are nearly always borderline cases. Moreover, many of the errors result from inevitable fluctuations in each child's subsequent development and to various accidental conditions, such as ill-health or inadequate motivation at the time of testing.

With adults formal testing is, as a rule, less satisfactory. Nevertheless, it is not without its value in occupational guidance and selection. Here the method of estimating the efficiency of the various procedures has to be modified. The commonest method is to adopt the device of matched groups. One batch of candidates is selected in the ordinary manner and the other on the basis of the test results. The after histories of both are then systematically compared. In the main the data obtained justify the value of scientific testing as an adjunct to other procedures. When tests are used for diagnosing individuals or for predicting their subsequent progress, it is essential that the marks or measurements should not be accepted in isolation from all other information. A single test scale, particularly if obtained during a group examination, may prove a precarious indication of the characteristic the investigator wishes to assess.

Tests used in industrial, educational, and military situations typically show validity coefficients between .30 and .60 in predicting on-the-job performance. This means that such tests account for only about 9%–36% of the variance in performance on any criterion; the margin for error in selection and placement is clearly large. But when interpreted in the light of other data (past history, family records, environmental conditions, observations of general behaviour, etc.) their value is unquestionable.

(Cy. B.)

III. TESTS OF PERSONALITY AND TEMPERAMENT

In personality testing the first major task—shared with all other kinds of psychological testing—is the construction of tests that are valid and reliable and that are addressed to significant aspects of individual behaviour. The second major task is the development of interpreters with sufficient diagnostic and interpretive skill to appraise the individual case. Attainment of the first goal will ordinarily require extensive research and statistical analysis (see *Construction and Standardization*, above). Attainment of the second, however, is more a matter of the intuition and insight of the test interpreter than of the particular tools or techniques of analysis employed. It is for this reason that so much stress is put upon the professional training of the practitioner in the field of personality testing.

An obvious problem in personality testing is the selection of the proper factors for measurement from among the seemingly endless number of traits, attitudes, values, behavioural tendencies, points of view, and other characteristics a person manifests; the next problem is that of organizing them so as to give rise to an integrated and functional view of this person as a distinct individual. The level of understanding desired rests on proper evaluation of three components: (1) the attributes of personality; (2) the structure or dynamic interplay of these attributes; and (3) the behavioural implications of this system of attributes.

G. W. Allport listed about 50 definitions of the term personality, drawn from philosophical, legal, sociological, and theological as well as psychological writings. Many of the definitions stressed the way in which the person is perceived by others. This emphasis, however, seems too restricted, for it neglects the inner, subjective components of personality and their implications for overt behaviour. An adequate view of personality must be broader, incorporating latent traits as well as those more manifest. It should also emphasize the organized pattern of traits and attributes underlying and determining the behaviour of the individual.

From this standpoint, temperament is seen as a factor or component of personality. Specifically, it refers to typical modes of reaction, states of energy, and moods. The descriptive adjective "capable" would refer to personality but not to temperament; the adjective "impulsive" would refer to both. Another broad term

often used in speaking of personality is "character." Following the above, character also is to be seen as an aspect of rather than as a synonym for personality. The emphasis in character is on morally sanctioned and approved attitudes and behaviour. (See also PERSONALITY; CHARACTER; TEMPERAMENT.)

The commonest unit of description and measurement of personality is the trait. A trait is an enduring quality showing itself in the typical way a person behaves in many different situations. All trait descriptions imply a basis of comparison with other persons, a dimension of variation. Thus most traits are present to some degree in most persons; the trait becomes salient only if it characterizes a person to a greater or lesser degree than the average. In personality analysis the psychologist looks for these significant departures from the norm; in personality testing one of the tasks is to specify units of variation for a trait and then to locate persons as high, average, or low.

A vexing problem in the psychology of traits is their number. Allport and H. S. Odbert assembled a list of 17,953 English adjectives used to describe specific modes of behaviour and thought. Each of these words represents a potential trait for the personality psychologist. Such a list obviously needs to be reduced in length if economy and efficiency of descriptive language are to be attained. One such attempt was made by R. B. Cattell, using the technique of factor analysis, a method developed first by Thurstone on the basis of work by Spearman. Cattell succeeded in defining what he believed to be the 12 "primary" trait dimensions of personality. These dimensions ranged from cyclothymic (voluble, emotionally expressive) v. schizothymic (withdrawn, reserved) through surgency (cheerful, buoyant) v. desurgency (listless, phlegmatic) to sophistication (cool, detached, aloof) v. simplicity (attentive to people, sentimental).

Another significant attempt to specify the major dimensions of variation in personality was that of H. A. Murray, who defined a set of needs said to have both motivational and orientational implications for individual behaviour. Examples from Murray's list are these: need:achievement, to succeed in something difficult, to rival and excel others; need:inavoidance, to avoid humiliation, to refrain from action through fear of failure; need:sentience, to seek and enjoy sensuous impressions.

Several other bases for the choice of terms to describe and analyze personality warrant citation. The language of diagnostic psychiatry has been a continuously important source of concepts. Personality tests for factors such as hypochondriasis (excessive preoccupation with bodily functions), paranoia (exaggerated and irrational distrust and sensitivity), and hypomania (overexcitability, improvident and unmodulated discharge of energy and impulse) are examples of this tradition. Systematic testing methods also have been based on the typology of personal values developed by E. Spranger, on recurrent and self-revelatory modes of perception (H. Rorschach) and on occupational choices and vocational preferences (E. K. Strong).

In the years since Binet's first test of intelligence was issued there has been a great increase in the numbers and kinds of testing instruments. A bibliography for such testing and rating scales published in 1939 contained 4,279 citations; a supplement published in 1946 contained 5,294. The number of such instruments available in the 1960s is greater than 6,000; it is therefore impossible to discuss any save the most important or most representative examples in this review.

A. EARLY TESTS OF PERSONALITY

1. Free Association.—One of the first methods systematically used as a test of personality was the free-association technique introduced by Galton in his studies at the London anthropometric laboratory which he founded in 1884. The free-association method was later used by the German psychiatrist Emil Kraepelin, who presented a list of words to psychiatric patients, requiring them to give in response the very first word that came to mind for each stimulus. The Swiss psychiatrist C. G. Jung (1910) developed a special stimulus list of 100 words for use in diagnosis of the "complexes" of unconscious conflict envisaged by his theory; various diagnostic indicators of inner conflict were enumerated, such

as delay or acceleration of response, inability to respond, facial grimaces, and changes of skin colour. A similar list was prepared by the U.S. investigators Grace Kent and A. J. Rosanoff (1910). Many other lists were later developed, but the two of Jung and Kent-Rosanoff continued to be the most widely used. (See also ASSOCIATION, MENTAL.)

2. Questionnaire.—Galton also can be said to have originated the questionnaire method, although a prominent early practitioner of the technique was G. S. Hall, particularly in his studies of developmental psychology and adolescence (1891, 1904). However, the prototype of the modern personality questionnaire was the Personal Data Sheet developed by R. S. Woodworth (1918) for use as a screening device to detect men psychologically unfit for military service. The Personal Data Sheet included 116 items selected from a much larger number of items on the basis of the correlation between each one and the total score for all the items. This method of inventory construction is called the internal consistency method and, although it provides no evidence of external validity, was widely followed in the development of other tests. The questions in the data sheet covered ten categories of distress, such as physical symptoms, fears, antisocial moods, and compulsions, and included items such as these: "Are you frightened in the middle of the night?" "Do you have continual itching in the face?" and "Does liquor make you quarrelsome?" The score on the test was simply the number of such items answered in the unfavourable or "disturbed" direction. Although at first very widely used, the Personal Data Sheet gradually was displaced by inventories covering more than one category or disposition and including items less obvious and susceptible of direct dissimulation.

One of the personality inventories used in testing of secondary school and university students is the Bell Adjustment Inventory, first published in 1934 by H. M. Bell; the inventory also has a less frequently used adult form. The device contains 140 questions of the "yes," "no," "?" response variety, attempting to assess personal adjustment under four categories (home, health, social, and emotional); it also yields a total score. The adult form includes the above plus 20 additional questions covering occupational adjustment. The inventory is employed as a quick diagnostic indicator of the extent and locus of a subject's problems, but is too transparent and easily falsified for use in settings where "faking" is likely to occur or where significant deficiencies of self-insight are to be expected.

Another questionnaire that has enjoyed wide usage is the Bernreuter Personality Inventory, first published by R. G. Bernreuter in 1931. In its original version this test contained four scales, each in itself the descendant of an earlier and independent test: neuroticism, self-sufficiency, introversion, and dominance. The 125 items in the test were taken from these earlier instruments and resemble those cited above for the Woodworth Personal Data Sheet. Many of the items contributed to the score on more than one of the scales, giving rise to a doubt concerning their statistical independence. A factor analysis of the test by J. C. Flanagan in 1935 suggested the presence of only two discriminable dimensions: self-confidence and sociability. Nonetheless, most users continued to score the test for the original four scales, occasionally using the two factors of Flanagan as additional scores.

Research analyses of the Bernreuter test showed it to have serious weaknesses; for example, its openness to "faking" and its inability to identify psychiatrically disturbed or maladjusted persons who are unaware of their problems or whose modes of self-defense cause them to minimize or deny their doubts and anxieties when asked to report on their well-being.

3. Ink Blot.—Experimentation with ink blots and interpretive responses given to more or less unstructured materials represents another theme in the development of methods for testing personality. Binet, the originator of the intelligence test, also conducted studies in this domain. A number of U.S. investigators at about the start of this century espoused the method, but tended to be more interested in it as a way of studying imagination and the "higher mental processes" than as a technique for personality analysis. Whipple's testing manual (1910) contained a description of ink-blot methods and instructions for their experimental

use. The major impetus to the development of this method, however, came from the Swiss psychiatrist H. Rorschach, who, on the basis of prolonged experimental tryout of various blots and various methods of administering them to subjects, evolved in 1921 a series of ten blots and a technique of administration and analysis that remain the most frequently used procedures in the field. Rorschach stressed the importance of formal and structural elements in response to the blots as well as the content of such responses. Following Rorschach's death shortly after the introduction of his method, the work was carried forward on the continent by his student E. Oberholzer and in the United States largely through the efforts of S. J. Beck and B. Klopfer.

4. Situational-Observational.—In the method of situational testing the subject is asked to carry out some task or to do a certain thing, his behaviour then being observed and rated or measured in some specified way. The performance requested may be one from everyday life (e.g., to participate in an impromptu discussion), or it may be quite alien to the subject's usual experience (e.g., interrogation concerning a make-believe crime by a hostile and disparaging investigator). The first extensive application of situational techniques was found in the work of H. Hartshorne, M. A. May, and their collaborators (1928-30). Their researches, done primarily with school children, attempted to derive quantitative indices of behaviour such as cheating, lying, stealing, cooperativeness, and persistence. Their results were so contradictory to the prevalent belief that conduct is merely the manifest expression of generalized traits (such as honesty, generosity, selfishness, etc.) that for several years other efforts to develop testing methods for these factors were inhibited.

Nonetheless, the situational-observational method began to take root, and a clear statement of its aims and purposes was made in a book published by the United States Office of Strategic Services psychological staff, *Assessment of Men: Selection of Personnel for the Office of Strategic Services* (1948; reissued 1963). The method, involving the intensive observation and study of the person over a two- or three-day period of time and utilizing a wide variety of techniques and testing aids, gradually came to be called that of personality assessment, and in the 1960s this approach was well established as a valuable technique for the appraisal of personality.

B. OBJECTIVE OR STRUCTURED TESTS

The weaknesses of the Woodworth test and other objective questionnaires are exceedingly difficult to avoid in tests constructed by internal consistency methods. In this approach, the test developer first writes or chooses the items for his test, and also decides how they should be scored so as to indicate "nervousness," "leadership," "occupational dissatisfaction," "poor morale," or whatever the factor is that he intends to appraise. The items are then put into a preliminary test, which is given to a sample of persons and scored. The individual items are next correlated with the total scores, the purpose being to discover any that do not have a significant correlation with the total; such items are eliminated from the test, the justification being that they do not covary with the general tendency being measured by the full set of items. The remaining items—those that correlate highest with each other—are retained for the final version of the test.

This psychometric purification results in a scale or test that represents well the view of the psychological trait that the test developer had in mind when he began his work. The method makes no secure provision, however, for correcting the developer's erroneous preconceptions as to which way items should be answered to indicate abnormality (if this is what he is seeking to measure) and for revealing which items are diagnostically useful. "Nervous" people do not always answer an item in the way one would expect from their symptomatology. For example, more often than not they may answer "false" to the item "Thoughts run through my head so that I cannot get to sleep at night," even though they have insomnia, while well-adjusted people may feel rather free to admit that they have this problem on occasion. Following the method of internal consistency, this item might be keyed "true" because it had a high correlation with total score, whereas a com-

parison of the answers with a nontest criterion of "nervousness" would reveal that denial of this common experience was the diagnostically more important response.

A contrasting mode of test development is the "known-group" or "empirical" method, in which the responses of externally classified groups (e.g., persons in a certain occupation, students nominated as outstanding leaders, diagnosed patients in a psychiatric hospital) are studied to determine empirically (by observation) which if any questionnaire responses differentiate the group from control or base-line groups. Such a method will automatically reduce the effect of preconceptions held by the test maker; furthermore, if his initial list of items is large and varied, the analysis will almost always uncover several new diagnostic indicators of the trait. The former (elimination of erroneous preconceptions) constitutes a distinct gain for test validity, where validity is taken to be the test's correspondence with the external nontest world; the latter (discovery of new diagnostic indicators) constitutes an equally important advantage.

1. SVIB.—Perhaps the leading example among tests that have used known groups in scale construction is E. K. Strong's Vocational Interest Blank (SVIB), first published in 1927. The inventory was continuously expanded and revised until by the 1960s scores for more than 50 different occupations could be obtained. A parallel Strong Vocational Interest Blank for women was brought out in 1935, this form being scorable for about 25 occupations. The male form of the SVIB contains 400 items, grouped into eight sections. The first five cover the categories of occupations, school subjects, amusements, miscellaneous activities, and peculiarities of people. Preferences are indicated for each item by circling the letter "L," "I," or "D" (for "like," "indifferent," or "dislike"). The last three sections of the device call for ranking of certain activities in order of preference, choosing options in pairs of items and the rating of own abilities and other characteristics.

Scoring keys were developed by studying the responses of persons successfully engaged in a specified occupation and then contrasting their item statistics with those obtained from a sample of men in general. Items that revealed statistically significant differences were selected and marked for scoring to stress the responses actually given by men in the particular occupation.

The test scores of a person who takes the SVIB are entered on a profile sheet that provides letter-grade equivalents ("A," "B," and "C") for each of his scores. An "A" rating signifies a high score, in the range usually observed among persons actually employed in the field; a "B" rating is in a more indeterminate range; and a "C" rating indicates a score significantly lower than those typically found for persons working in the field. These letter ratings, it should be emphasized, are indications of the correspondence between a person's interests and those of persons in the occupational fields; they do not necessarily indicate anything about his aptitudes for work in those fields. The co-variation of scores for the different occupational keys permitted the grouping of scales on the profile sheet into "job families." For example, scores on the keys for lawyer, advertising man, and author-journalist usually vary concurrently and are therefore grouped together into what test interpreters call the verbal-linguistic cluster. These scale clusters on the profile sheet have allowed some users of the Strong test to develop complex forms of profile interpretation and even a form of personality analysis that goes far beyond the simple rating of areas of vocational choice and vocational rejection.

The profile sheet also provides for the listing of several scores besides those directly pertaining to a specific occupation. (1) The occupational-level scale reflects differences between interests of unskilled and semiskilled workers on the one hand and those of business and professional men on the other. (2) The interest-maturity scale was based on a contrast between males of age 15 and those of age 25 (the age at which Strong found a fairly stable crystallization of interest patterns). (3) A specialization-level scale reflects interests characteristic of medical specialists and of research workers in other scientific fields. (4) Finally, a masculinity-femininity scale shows the degree of similarity between the person's interests and those characteristic of men or of women, respectively.

2. Kuder Preference Record.—This test, first begun in 1934 by G. F. Kuder, and issued in various forms since then (1939, 1942, 1948), also yields scores indicative of occupational interests. The vocational form of the test (Form C) includes 168 item triads describing three different activities or interests. The respondent selects in each triad the one he likes most and the one he likes least. On the basis first of logical groupings of the items and later of extensive statistical analysis ten interest scales were developed: outdoor (agricultural, naturalistic), mechanical, computational, scientific, persuasive, artistic, literary, musical, social service, and clerical. A verification scale to detect carelessness and failure to observe instructions is also included. A profile sheet for the record provides for an automatic conversion of raw scores to percentiles, and the profile pattern gives a visual picture of the high, average, and low rankings over the ten categories.

Both the Strong and the Kuder tests are very popular. The Kuder has the advantage of a smaller and simpler set of categories and lends itself to situations where self-interpretation of scores is a necessity. The Strong test, however, contains a greater fund of information and is also supported by a significantly greater amount of validating research literature.

3. Minnesota Multiphasic.—The Minnesota Multiphasic Personality Inventory of S. R. Hathaway and J. C. McKinley, first published in 1943, contains 550 true-false questions, many borrowed from earlier tests such as the Woodworth Personal Data Sheet and the Bernreuter Personality Inventory. It also includes, however, original items more directly pertinent to the areas typically examined by a thorough diagnostic interview in a psychiatric setting; the questions cover 26 such categories.

Fourteen scores are reported on the standard profile for this test. These scales and the diagnostic aim of each are summarized as follows: (1) Cannot say—to identify records rendered invalid by the exclusion of too many items. (2) Lie—items involving improbable claims to moral virtue and rectitude, the answering of which in the scored direction implies an attempt to falsify or the presence of strong repressive-constrictive trends. (3) "K"—reflects the subject's habitual style of verbal behaviour and self-description, ranging from restrictive prudence and inhibition at one end to crudity and lack of restraint at the other; scores on certain of the other scales are adjusted up or down according to the person's score on the "K" scale. (4) "F"—includes highly unusual and atypical response choices, serving to identify records with an undue number of answers of an unusual or infrequent kind whether due to carelessness, deliberate falsification, or distorted thought processes. (5) Hypochondriasis—reflects somatic complaints and preoccupation with bodily functions. (6) Depression—indicative of poor morale, feelings of depression, and worry. (7) Hysteria—reveals tendencies toward repressive, immature emotional life, and bodily expressions of psychological conflict. (8) Psychopathic deviate—identifies persons of disruptive, rebellious temperament who find it hard to accept rules, restraints, and orderly habits of life. (9) Masculinity-femininity—attempts to detect deviations of interests and outlook toward those characteristic of the opposite sex. (10) Paranoia—indicates attitudes of undue or irrational suspiciousness coupled with exaggerated sensitivity. (11) Psychasthenia—a heterogeneous set of obsessions, compulsions, and phobias synthesized as a general index of agitation and perplexity. (12) Schizophrenia—reveals trends toward alienation from self and others, loss of self-direction, and frankly delusional thought content. (13) Hypomania—a gauge of emotional expansiveness, excitability, and accelerated tempo of thought and behaviour. (14) Social introversion—seeks to identify persons of diffident, anxious, and retiring disposition.

These 14 scores are plotted on a profile sheet that provides an automatic conversion of the raw score totals to standard scores that have been statistically adjusted to give a mean score of 50 and standard deviation of 10; this permits direct comparisons among scales. The profile of scale scores for the Minnesota Multiphasic, like that for the SVIB, lends itself to complex configurational interpretations; psychologists use the inventory to prepare personality analyses of patients tested in clinics and hospitals. The inventory is principally oriented toward matters of psycho-

pathology and morbidity and has shown its greatest (but limited) validity when applied to clinical and psychiatric problems; it has shown less utility when applied to problems of normal behaviour and everyday life.

Personality inventories more directly concerned with the functioning of normal persons, although later in appearance than those concerned with neuroticism and inner conflicts, were increasing steadily in use during the 1960s. One such instrument is the Edwards Personal Preference Schedule, published in 1954. It seeks to measure variables drawn from Murray's theories (*see above*); *e.g.*, need: nurturance and need: affiliation. A second instrument is the California Psychological Inventory, published in 1956. This inventory is addressed to "folk concepts"; *i.e.*, attributes of personality such as dominance, responsibility, and social presence which arise directly out of social life.

C. STUDY OF VALUES

The Study of Values was first introduced by Allport and P. E. Vernon in 1931, and then revised in 1951 by Allport, Vernon, and G. Lindzey. The test is derived from a theory of E. Spranger, postulating that in the life of each person a great single unifying theme or value may be discovered. The Study of Values seeks to measure the relative strength of six such values: (1) theoretical—having a dominant interest in the discovery of truth, valuing critical, rational, and logical thinking; (2) economic—primarily interested in utility, in the practicality and efficiency of things; (3) aesthetic—places highest value on form and harmony, seeks out and prefers artistic experience; (4) social—directed toward altruism and philanthropy, values the welfare of others and of mankind; (5) political—is power oriented, seeks esteem and renown, control over others; (5) religious—concerned with unity, the mystic nature of existence and of the cosmos.

The device contains 45 questions presenting either two or four propositions that the subject must rate in order of preference. An example is the following: "In your opinion, can a man who works in business all the week best spend Sunday in: (a) trying to educate himself by reading serious books; (b) trying to win at golf, or racing; (c) going to an orchestral concert; (d) hearing a really good sermon." The classification of these options under the value types of theoretical, political, aesthetic, and religious obviously is not difficult, and this very ease reflects one of the limitations of the test—its openness to deliberate dissimulation. Another limitation resides more in the theory than in the test itself; that is, in the restricted applicability of the six value types. Even insofar as the unity theme concept in personality is correct, these particular six values contain an aristocratic bias in that they apply more to persons of intellectual, ratiocinative temperament than to more ordinary individuals.

D. FACTOR ANALYSIS

The inventories discussed up to this point have dealt with either (1) dimensions of measurement taken directly from the settings in which the test is to be used (*e.g.*, the SVIB) or (2) with dimensions taken from theoretical systems that were offered to explain and account for human behaviour (*e.g.*, the Study of Values). In inventories developed by the technique of factor analysis a markedly different basis of choice is to be seen. In factor-analytic tests the factors to be measured are not necessarily those that seem on the surface most relevant to a particular setting or those that a previous theorist has talked about; on the contrary, the dimensions of choice seem to be those that most economically summarize the variations of response to be found among the components of the testing battery.

The underlying logic of factor analysis is mathematical, and its principle of faith is that mathematically basic test dimensions will also be psychologically basic. Suppose that a number of experimental tests of "personal adjustment" were tried out and then correlations among scores on the experimental tests were computed. Undoubtedly some of the tests would overlap each other, and the full set would contain an unnecessary amount of duplication. The aim of factor analysis in this example would be to specify the extent of such redundancy and then to indicate the

minimum number of underlying factors that could be used mathematically to account for all the scores found in the experimental battery. Measurement of these underlying factors could be said to be a more efficient and more valid way of assessing the domain of personal adjustment.

The technical methods of factor analysis are mathematically complex and difficult, but their purpose is simple: to identify the dimensions that will represent most economically the set of interrelationships given by a battery of test scores or test items. At first discovery, the factors may seem strange or different from the usual ways in which the test elements have been discussed, although this is partly a function of the names the analyst chooses to assign to his factors. A second, more significant, difficulty is that the new mathematical factors may have less accuracy as predictors of nontest behaviour than the mathematically impure tests the factors are designed to replace. In such instances the factor analyst seeks an optimum combination of factor-pure tests from which a valid prediction in a specific practical situation can be made.

Perhaps the leading U.S. exponent of factor-analytic methods in personality test development has been J. P. Guilford, whose various inventories are used widely and are among the most important examples of factorially based devices. The Inventory of Factors STDCR (1940) included scales for social introversion, thinking introversion, depression, cycloid disposition, and rathymia (happy-go-lucky, carefree). The Guilford-Martin Inventory of Factors GAMIN (1943) covered the factors of general activity, ascendance, masculinity, inferiority, and nervousness. A third test, the Guilford-Martin Personnel Inventory (1943), included scales for the factors of objectivity, co-operativeness, and agreeableness. A later test, the Guilford-Zimmerman Temperament Survey (1949), included 300 questions scaled for ten factors: general activity, restraint, ascendance, sociability, emotional stability, objectivity, friendliness, thoughtfulness, personal relations, and masculinity.

Another leading exponent of factorial technique is R. B. Cattell, whose most widely used inventory was the Sixteen Personality Factor Questionnaire (1950). The inventory had two parallel forms, each with 187 items; a third form having 105 items was later added. Several examples from Cattell's designations of the 16 scales can be given: cyclothymia *v.* schizothymia; general intelligence *v.* mental defect; emotional stability *v.* general neuroticism; surgency *v.* desurgency; bohemianism *v.* practical concernedness; sophistication *v.* rough simplicity; and anxious insecurity *v.* placid self-confidence.

E. PROJECTIVE METHODS

Although projective methods for studying personality were used by Galton, Jung, Kent and Rosanoff, and others, as mentioned above, it was not until the appearance of Rorschach's ink-blot technique in 1921 that the approach began its rise to popularity. Even in Rorschach's own work, however, the theoretical implications of the method were little developed, for he saw himself as an empirical scientist engaged in the development of a diagnostic tool having practical objectives. The first significant formulation of the theory and point of view of projective testing was given by L. K. Frank (1939). The fundamental theorem is that when confronted with unstructured stimuli the person will impose structure on them in such a way as to reflect his own needs and impulses; the subject's responses therefore are expected to serve as guides to his private world of fantasy, his attitudes, fears, aspirations, and the like.

1. Theory of Projective Methods.—The word projection in reference to this process and to this category of tests is somewhat equivocal. There has been a tendency to identify the theorem of projective testing with the psychoanalytic (Freudian) concept of projection; *i.e.*, with the mode of ego defense in which unacceptable impulses are externalized and attributed to others or to outside agents (*see DEFENSE MECHANISMS*). However, the projective test responses are by no means delimited to denied and expulsed ("projected") psychological material of this sort, or even primarily focused upon it.

Another meaning of projection is simply that which stands out

from its surroundings, that which extends beyond something else. This meaning of the term is somewhat applicable to projective tests insofar as the ambiguity of the stimuli and the freedom of the test situation often do permit the appearance of highly salient mental content, those concerns that are most active and impelling in the mental life of the subject at the time of testing.

However, a third meaning of projective, the geometric or cartographical one, is probably closest to the implications of Frank's thesis. In this meaning the external representation is not considered as merely a general derivative of its originating source, but as a specific point-for-point rendition of it. Thus, a geometric drawing gives an exact representation of the three-dimensional object from which it is made, and a map is intended as a precise guide to a given section of terrain. If to an amorphous ink blot a person replies, "Eyes of bloody fire," and then adds, "but it could be a dear little dancing mouse," the discontinuity is only apparent; each response represents inner experience, and the path from the first to the second (*i.e.*, the relation between them) is as determined and meaningful in the experiential topography as the interval between points A and B in the geographic counterpart. The theoretical aim of the projective test is therefore no less ambitious than this: to chart in a faithful and interpretable way the full range and depth of the inner life of a person.

In practice, the classification of tests as projective or nonprojective has followed lines of custom and convenience not always in accord with consistent interpretation of the theory. Freedom for the subject to respond as he wishes would seem to be an essential element of the projective method if crucial features of the subject's inner life are to have full opportunity to manifest themselves. The instructions in the Rorschach test, where the subject is asked merely to report on what he sees, satisfy this requirement very well; on the other hand, an activity check list where the subject simply marks "like" and "dislike" does not. The Rorschach test is therefore properly classified as a projective test, and the activity check list as nonprojective. However, one of the tests classified by custom as projective, the Szondi test, requires the subject to make this same "like" *v.* "dislike" response to a series of photographs of European mental hospital patients; the Szondi test therefore has no more and no less freedom of response than the nonprojective activity check list.

This logical confusion is seen again in the factor of ambiguity of stimulus materials, held to be an essential condition for projective responses. The ink blots of the Rorschach test are for the most part amorphous and lacking in readily perceived meaning. Yet the geometrical figures that the subject copies in the (projective) Bender Gestalt test are clear and precise, certainly less ambiguous in point of fact than the more difficult items in a (nonprojective) test of spatial visualization. On this particular dimension of stimulus ambiguity, therefore, the nonprojective test of spatial visualization would have to be rated as closer to the projective test ideal than the projective Bender Gestalt.

2. Rorschach Test.—The Rorschach ink-blot test contains ten stimulus cards: five achromatic cards having only shades of gray and black, and five chromatic blots incorporating various colours.

The cards are presented to the subject in a standard sequence with brief instructions on the order of: "I am going to show you a series of ink blots, one at a time. The blots do not necessarily represent specific things; different people see different things in them. Would you please look at this blot and tell me what you see, what it makes you think of?" The examiner keeps a record from this point on of comments, responses, time consumed, how the cards are held and turned, etc. Questions are answered in noncommittal fashion; *e.g.*, "Whatever comes to your mind," "It's entirely up to you."

Analysis of the test covers four principal categories:

1. The first of these is location, the part or parts of the blot

utilized in the response. The main elements in this category are the "whole" response, which involves the complete blot, the large detail, and the small detail. The usual protocol (record of responses) strikes a balance among these three components; emphasis on one or another is seen as evidence for significant modes of personality functioning. For example, concentration on large, common details is held to be characteristic of the mundane, practical, fact-centred personality.

2. The second main scoring category concerns the determinants of the response; *i.e.*, whether form, colour, apparent texture of the surface, shadings, or other factors influenced the perception. Here again a balance among the elements ordinarily prevails, and deviations from the base line are said to hint of salient trends in the personality. An excitable, uninhibited, effervescent person might have many responses in which colour is a vital feature; an aggressive, explosive person might show form elements subordinated to colour in nearly every instance. Where he is doubtful about what qualities in the blot have given rise to a certain response, the examiner makes discreet inquiries. For example, to a certain red-coloured portion of a blot the subject says, "And there I see a bow tie." The examiner, returning to this response after finishing the ten blots, might ask, "Can you tell me why that part is a bow tie?" If the respondent answers, "Why, because it's shaped like one, that's why," the examiner might go on to ask, "Would it still look like a bow tie if it was entirely black?" The form-dominated perceiver would probably now respond "Of course," the colour-dominated, "Certainly not."

3. The third category is that of the content of the response. Here again common clusters appear. Most records contain some references to human beings, to animals, and to natural phenomena of one sort or another. The absence of any of these or overconcentration on a particular one provides a basis for interpretation.

4. A fourth category, more or less included in the interpretations of the first three but still listed as a separate feature in the scoring, has to do with the popularity or originality of each response. For certain blots certain responses are so typically given that they are labeled "populars." Persons whose perceptual habits and reactions are similar to those of others will give an appreciable number of such "popular" replies during the course of the testing. Psychotic or deranged subjects might give very few or none at all. At the other end of the scale are responses that are seldom encountered or that the examiner hears for the first time. Such responses are called "original." A further classification into good quality (O+), average quality (O) or poor quality (O-) is necessary in order to distinguish between creatively original perceptions and those involving distorted or warped conceptions.

On the basis of these and other ancillary scoring procedures the Rorschach analyst attempts to synthesize a model of the functional psychology of the person, one that depicts the formal properties of his personality (*e.g.*, intellectual ability, introversion-extroversion, inhibitions, constraints, level of affective energy, etc.) as well as his particular concerns and problems. The validity of this final formulation is said to rest in large part on the skill and wisdom of the examining psychologist.

However, H. J. Eysenck (University of London), writing in the *Fifth Mental Measurements Yearbook*, concluded that the Rorschach ink-blot test has yet to show "... scientific or practical value." And Beck, a leading U.S. exponent of the test's use, wrote in the same volume that any conclusions derived from its use are to be considered "... not as facts but as hypotheses." In the 1960s controversy over the trustworthiness of the Rorschach as a test and the competence of its users to draw valid conclusions from the protocols continued to grow.

3. **Thematic Apperception Test.**—The second most widely used test of the projective group is the Thematic Apperception Test (TAT), first issued in 1935 by Murray and Christiana D. Morgan. In the TAT, pictures are presented on cards to the subject, who is asked to make up a story having an antecedent, a plot, and a resolution. Stress is laid on the concept of "imagination" in instructions, with the offhand comment being made that "imagination is one form of intelligence." There are 31 pictures in

INK BLOT, SIMILAR TO THOSE USED IN RORSCHACH'S TEST

BY COURTESY OF STEPHEN C. CLARK

"SUNLIGHT IN A CAFETERIA" BY EDWARD HOPPER, A PAINTING SIMILAR TO THOSE USED IN THEMATIC APPERCEPTION TESTS (see TEXT)

all, these being grouped into special subsets of 20 each for younger and older subjects, male or female. The manual calls for two one-hour testing sessions, ten cards being administered at each. The more unusual and dramatic pictures are reserved for the second sitting, along with one entirely blank card. The subject ordinarily tells his stories aloud, the examiner copying them verbatim. However, all these procedural matters vary widely in practice, depending upon the examiner; the variability in this respect is much greater than for other tests of wide usage.

In the analysis of test results there is also much less standardization in the TAT than in other tests. Some examiners have utilized Murray's "need-press" system of concepts or variations of it; some apply psychoanalytic notions of defense, repression, projection, etc.; others merely attempt a subjective-intuitive résumé of the personality of the storyteller. For special purposes the stories can be scrutinized for particular themes or qualities; one such scoring, for example, is based upon the number of manifestations of the need for achievement; another is based on appraisal of the stories for their level of originality. The test method also has been applied in anthropological field studies to help shed light, for example, on child-rearing attitudes, on moral codes and sanctions, and on philosophical values. Despite these applications, evidence for the validity of the TAT is sparser and more questionable than that for the Rorschach.

F. OTHER METHODS

There are literally hundreds of additional projective methods for the assessment of personality that could be discussed in a complete review of the topic. A few examples are given below, classified by type of task or method of testing.

1. Constitutive Methods.—In these the subject imposes a form or structure upon an amorphous or plastic substance or upon partially structured or semiorganized fields. Examples are the Rorschach test; Hans Zulliger's three-blot ink-blot test modeled after the Rorschach; the sentence-completion method proposed by A. F. Payne in 1928; and finger painting as introduced by Ruth F. Shaw in 1930.

2. Constructive Methods.—In these the subject is asked to build or construct something, the implication being that some of the organizing principles in his own personality will be manifest in his test constructions. M. Lowenfeld's Mosaic Test, introduced in 1929, is an example. The subject is given a set of 465 small wooden blocks of six colours and five shapes and asked to "make anything you like out of the pieces." The mosaics can then be evaluated on some 23 factors, including such characteristics as concreteness *v.* abstraction, over-all harmony of design, simplicity *v.* complexity, and emphasis on form or colour.

3. Interpretive Methods.—In these the subject is asked to tell what a specific stimulus, such as a picture, suggests or means to him. The Thematic Apperception Test provides one example of the type. The Four-Picture Test of the Dutch psychologist

D. J. van Lennep, in which the subject is requested to tell a story incorporating the people and backgrounds shown in four pictures, is another.

4. Cathartic Methods.—In these methods the aim is to release pent-up emotions and feelings in such a way as to permit interpretation and personality diagnosis. An example is the "therapeutic doll" of D. M. Levy, which the subject may dismember, cuddle, maltreat, etc., at will.

5. Refractive Methods.—This category includes the use of any conventionalized mode of communication or expression, verbal or written, as a basis for personality assessment. Handwriting analysis (graphology) is a prominent example (see HANDWRITING). (H. G. G.)

IV. ATTITUDE MEASUREMENT

An attitude may be measured as the degree of positive or negative feeling associated with some psychological object or event (see ATTITUDE). The psychological object may be a job, a racial or ethnic group, a governmental policy, or a book title; it may be a person, a thing, an institution, or an idea (see PUBLIC OPINION; FLAVOUR: *Flavour Testing*; VOTING BEHAVIOUR; PSYCHOLOGY, SOCIAL).

A. APPROACHES

One possible approach to attitude measurement entails asking respondents direct questions demanding "yes" or "no" answers. This approach often has been used, with varying degrees of success, in the assessment of public opinion to predict, say, voting behaviour. Often it results in a large proportion of "don't know" or "undecided" responses, difficult to evaluate. Not infrequently, particularly on emotionally tinged public issues, respondents either consciously or unconsciously distort their replies, yielding results biased in the direction of the popular or socially approved response. These difficulties have prompted the development of less direct procedures for measuring attitudes.

An attitude schedule is a set of carefully constructed statements about a psychological object, together with some device, such as a rating scale, by which the subjects express their feeling toward each statement. Methods of attitude measurement differ, one from another, primarily in the means for constructing and selecting statements to be included on the schedule. The three main approaches to attitude measurement may be distinguished by noting whether the focus is upon the statements, the subjects, or the responses.

1. Methods Focusing on Statements.—These methods utilize judgments from a group of respondents to scale the attitude statements. Subsequently the scale values of the statements may be used to locate any individual on the attitude continuum on the basis of his responses to the schedule.

Procedures for measuring attitudes were pioneered by Thurstone, through a series of articles and monographs beginning in 1927. Thurstone extended the psychophysical methods (*q.v.*) by proposing a model for scaling psychological magnitudes of stimuli independent of any corresponding physical stimulus magnitudes. The class of methods including those proposed by Thurstone, all of which are independent of physical measurement, are known as the psychological scaling methods.

Paired Comparisons.—Of the psychological scaling methods, the earliest is the method of paired comparisons. In applying this method to the selection of statements for attitude measurement, statements are presented in pairs, with judges instructed to select that statement of each pair which they view as indicating a more favourable attitude toward the psychological object in question. For example, in selecting items for a schedule designed to measure attitude toward public censorship, the following two items might be paired: (1) "to protect the public it sometimes is necessary that censorship be exercised"; (2) "books and plays should be subject to moral censorship." Each respondent would be asked to select statement (1) or (2) as representing a more favourable attitude toward public censorship.

As presented to a sample of judges, each statement is paired with every other statement. Proportions of responses are gen-

erated of the form P_{ij} , the proportion of judgments that statement i is more favourable than statement j ; these serve as the basic data for application of the method. Data are treated by Thurstone's law of comparative judgment, a theoretical model transforming the proportions and operating on them so as to provide numerical scale values associated with each attitude statement. (In the simplest application of the model, it is assumed that affective values toward each statement have a normal distribution in the population of respondents and that the population variances and covariances of those distributions all are equal.)

Successive Intervals.—A related method for selecting attitude statements is the method of successive intervals, also suggested by Thurstone. Each separate statement is rated by every member of a group of judges to indicate favourability of attitude implied by the statement, the rating being in the form of a check mark in one of several response categories. Categories are defined to extend from "extremely unfavourable" to "extremely favourable," with intermediate categories suggesting more moderate attitudes. A law of categorical judgment here provides the model by which proportions of category ratings are transformed and yield scale values indicating degrees of attitude associated with the statements. Once again it is assumed that in the population attitudes are normally distributed. The method of successive categories has the advantage of providing quantitative estimates of the degree of ambiguity of attitude for each statement (indicated by the variances of distributions of judgments, measured on the attitude continuum). Such estimates are valuable for selecting statements to be included on an attitude schedule. Because of its theoretical advantages, the method of successive intervals has largely replaced the similar method of equal appearing intervals for construction of attitude schedules.

After scale values are assigned for each attitude statement and those to be put on a schedule are selected, the problem remains to estimate the attitude of individual respondents. A simple procedure is to present the schedule to each individual with instructions to check those statements with which he agrees. An average of the scale values for those items checked serves to locate the individual on the attitude continuum.

2. Method Focusing on Subjects.—A method proposed by Rensis Likert treats attitude statements much on the order of objective test items. An attitude schedule is constructed from a group of statements (with unknown scale values) selected to represent either favourable or unfavourable attitudes toward a psychological object or event. For each statement, subjects are instructed to respond by checking one of several possible response categories; e.g., "strongly agree," "agree," "uncertain," "disagree," or "strongly disagree." Likert suggested the arbitrary assignment of weights to these categories: 4, 3, 2, 1, 0, respectively, when statements convey a favourable attitude; 0, 1, 2, 3, 4, respectively, for unfavourable statements. For a given schedule, an attitude score is found for every subject simply by summing the weights associated with the responses of that subject. The approach is aimed at the direct assignment of attitude scores to individual subjects, avoiding the intervening step of assigning scale values to statements.

The Likert method often has been implemented by utilizing techniques of item analysis, borrowed from objective psychological test theory, to select appropriate statements for a refined final form of attitude schedule.

Both the Likert and Thurstone methods have often been used in practical efforts to measure attitudes. The several studies comparing results of the two approaches fail to show marked superiority of either approach over the other. Theory underlying the judgment methods of Thurstone is somewhat more completely defined, and in accordance with the theoretical measurement model, application of the Thurstone methods yields scores with wider general interpretations as numbers (as opposed to numerals representing order relations but not distance along an attitude continuum).

3. Methods Focusing on Responses.—In these methods an attempt is made to assign scale values to both subjects and statements from a single administration of the statements to the sub-

jects. The methods demand a set of attitude statements which vary along a single psychological dimension and assume subjects' responses to depend only upon their positions on this same dimension.

Scalogram Analysis.—One prominent response method is scalogram analysis, proposed by Louis Guttman. In applying scalogram analysis, it is assumed that any subject asked to accept or reject a set of attitude statements will accept all those with scale values at or below that point on the attitude continuum at which the subject is located, rejecting those statements with scale values higher than his own location. Consider the following four statements, listed in the order of increasingly favourable attitude toward cold climate.

- A. I am able to tolerate occasional cold weather.
- B. At times I enjoy cold weather.
- C. I would enjoy living where the climate is one of cold winters.
- D. I revel in cold weather, and would choose to live only in an area with cold climate.

For this set of sentences, anyone accepting the most extremely favourable statement D also would be expected to accept the statements reflecting a more moderate positive attitude toward cold climate, A, B, and C; a person accepting statement C also would be expected to accept A and B; and for someone accepting statement B, acceptance of A also would be anticipated. Conversely, if one rejects statement B, it is typically predicted that he will reject statements C and D. Under these conditions, the statements are said to be scalable. While there are 16 possible response patterns, patterns of acceptance (+) or rejection (0) among four statements, only 5 of these (in general, $n + 1$, where n is the number of statements) are expected to occur for four scalable statements:

Pattern	Statement			
	A	B	C	D
1	0	0	0	0
2	+	0	0	0
3	+	+	0	0
4	+	+	+	0
5	+	+	+	+

Subjects thus are divided, by responses to the four statements, into five groups classified according to favourability of attitude. Statements also become ordered in terms of the attitude variable by the observed response pattern.

Unfolding Technique.—A second response method for attitude measurement, known as the unfolding technique, was proposed by Clyde H. Coombs. Subjects are asked to rank a set of attitude statements according to the extent of their agreement with each. Analysis of such rankings yields information regarding the attitude of the subject relative to the set of statements.

Let the letters A, B, C, and D represent four attitude statements, listed in order from unfavourable to favourable attitude. A given subject S might rank the statements in the order C, D, B, A in terms of his agreement with them. By "unfolding" the rank order, the investigator could achieve a conception of the relative locations of statements and subject on the attitude continuum. The following portrayal is consistent with S's ordering of agreement with the four statements. The line segment represents the attitude continuum, progressing from unfavourable, on the left, to favourable, on the right.

The rank order assigned the statements by a given subject is interpreted as the order of distances between statement and subject on the attitude continuum and thus serves to locate (within a narrow range of values) the affective position of the subject relative to the locations of the statements. Analysis of responses from a group of subjects allows more definite estimates of the locations of statements.

4. Internal Consistency, Reliability, and Validity.—Each of the prominent methods for attitude measurement mentioned above includes means for checking the internal consistency of the method. In addition, reliability of measurement may be deter-

mined; numerous applications have verified that consistent (*i.e.*, reliable) measures of attitude may be obtained. A thorny problem, however, is that of determining the validity of attitude measurement. Immediately the investigator is faced with the task of specifying a behavioural criterion against which validity may be assessed. Except for instances in which attitudes are expressed through political action (*e.g.*, voting behaviour), instances of successful specification of such criteria are rare. A few studies indicate that these methods of attitude measurement exhibit at least greater validity than that attending the direct questioning of respondents.

B. CONSUMER PREFERENCE MEASUREMENT

Closely related to attitude measurement is the measurement of consumer preference, or acceptance of consumer products. However, the primary aim is somewhat distinct from that of attitude measurement: attention is directed toward the degree of acceptance of a product, judged by numerous consumers, rather than toward the placement of a person along a psychological continuum.

Psychological scaling methods that focus upon stimuli (analogous to statements in attitude measurement) are ideally suited to the aim of consumer preference measurement. These methods yield scale values associated with each stimulus rated or judged by a consumer sample. Stimuli might be food items, items of apparel, or other consumer products. By the method of paired comparison or the method of successive intervals it becomes possible quantitatively to evaluate the relative preferences displayed for a group of such items, and to estimate degree of acceptance of the items by a population of consumers (when the judging group is a random sample from that population).

An interesting application of models for consumer preference measurement allows prediction of consumer choice of competing products on an open market, or even prediction of relative purchase of each of several competing products when these are offered at different (known) costs to the consumer. For the latter problem, there enters the question of (negative) utility of money, which presumably combines with preference for the commodities to dictate proportions of purchase of each. Exploratory research on these problems suggests that the measurement methods are highly reliable and provide a useful quantitative model for estimation of consumer choice behaviour.

1. Multidimensional Scaling.—An extension of the psychological scaling methods not only provides conclusions concerning the distribution of sensory preferences among product samples, but also serves to indicate the (linearly independent) psychological components of the general sensory distinctions. This extension is known as multidimensional scaling, since it yields a solution for the several psychological dimensions responsible for the general differences in preference among stimuli. As an example, consider five distinct samples of coffee, to be evaluated for general flavour characteristics. Preference values could be obtained using the method of paired comparisons, presenting samples in pairs to a group of judges. There are ten pairs of the five samples (in general, $n(n-1)/2$ pairs of n stimuli); for each pair the proportion of judges indicating preferred flavour for each of the two brews of coffee would be determined. Application of the law of comparative judgment would yield solution of general preference scale values for each of the five samples.

Now the coffee samples could be presented again, this time utilizing the method of triads. Samples are presented in groups of three, with judges instructed to determine relative degree of similarity between pairs of samples within the triad. ("Stimulus i is more similar to stimulus j than to stimulus k .") With five stimuli, there are ten triads (in general, $n(n-1)(n-2)/6$ triads for n stimuli), and for each triad, three judgments are required, since each stimulus is compared with the stimuli of every other pair. The result of such an experimental procedure is the generation of n matrices of proportions, one for every stimulus sample, each of order $n \times n$. The elements of the i th matrix take the form p_{jk} , the proportion of times stimulus i is judged more similar to stimulus j than to stimulus k .

The proportion p_{jk} is postulated to depend upon the difference

between distances d_{ij} and d_{ik} , where d_{ij} represents (affective) distance of stimulus i from stimulus j , and d_{ik} represents distance between stimuli i and k . Assuming the distribution of differences in distance, $(d_{ij} - d_{ik})$ to be normal in the population, with equal variances and covariances, a solution is provided for every distance of the form d_{ij} . Once all such distances are computed, imposition of a spatial model (*e.g.*, assuming analogy to Euclidean space) will serve to determine the minimum number of dimensions required to account simultaneously for all empirically derived distances. Analysis of the configuration of interstimulus distances within the space may provide clues concerning the psychological characteristics of the dimensions.

2. Detection of Sensory Differences in Consumer Products.

—In numerous consumer industries, sensory characteristics of the product assume great importance. For manufacturers of processed foods and beverages, perfumes, colour reproductions, to name only a few, the quality of the product depends largely upon its sensory characteristics. Industrial testing for control of sensory characteristics of products has made considerable use of the psychophysical methods, particularly of the constant method.

A typical problem is that of assuring uniformity of the product. Not always does strict uniformity necessarily result from careful control of ingredients; minor variations in climatic conditions, time of preparation, storage conditions, and many other factors as well as quality and quantity of ingredients may affect the product. To assure no major variability in the product as marketed, sensory tests often are conducted. New batches of the product typically are compared with a standard batch, known to be of acceptable quality. In the case of foods and beverages, this constitutes taste testing for flavour characteristics. Samples of the product are judged in pairs, often by expertly trained judges. One member of each pair is the standard, the other is called the variable. The task of the tasters is to judge, for each pair, which is the sweeter, saltier, more pleasant, more bitter, or the like. On the basis of numerous ratings, proportions of such judgments are obtained for each variable as compared with the standard. Statistical procedures are available for guiding the decision concerning acceptability of quality. For example, it might be decided that a batch would be unacceptable if as many as 5% of consumers were to detect a deficiency in the product as compared with the usual standards. Application of the constant method and related statistical tests would serve to yield a decision concerning quality of each batch in terms of such a criterion. A method of analysis nearly identical to that of the constant method of psychophysics is the probit method of biometrics, developed in England by Fisher and D. J. Finney, in the United States by C. I. Bliss.

The psychophysical methods have proved useful not only for quality control of a product; they also are frequently applied to the development of improved consumer items. In this application, detection of a difference in a given direction, that the new product has more desirable characteristics than the old, serves as evidence upon which the new product may be marketed, either replacing the old or competing with it with some assurance that the new product will maintain a favourable competitive position.

PSYCHOLOGICAL WARFARE consists of the use of propaganda against an enemy, together with such military, economic, or political measures as the propaganda may require. Though often looked upon as a modern invention, it is as old as history. The conquests of Genghis Khan were aided by expertly planted rumours about the large numbers of ferocious Mongol horsemen in the khan's army. False though they were, these rumours frightened the enemy. Centuries later, in the American

TACTICAL PROPAGANDA ISSUED BY THE COLONIAL COMMAND DURING THE BATTLES FOR BOSTON. LEAFLET IS AN INVITATION TO THE BRITISH TROOPS TO DESERT

Revolution, Thomas Paine's *Common Sense* was but one of many examples of pamphlets and leaflets used to strengthen the colonists' will to fight.

In its modern form, consisting of the application of mass communications techniques to strategy and warfare, psychological warfare differs from the military propaganda of the past in two ways: it is proportionately a larger ingredient of the whole process of war; and modern scientific advances in communications, such as high-speed printing and radio, together with important developments in the fields of public-opinion analysis and the prediction of mass behaviour, make psychological warfare more nearly manageable and predictable than techniques used in the past.

Within armies, psychological warfare includes the training and equipping of specialized units in peacetime armed forces and the application of these skills to military situations when action comes. It is most effective when the entire army knows of its availability and value. The short form of the term, psywar, spread through the U.S. armed forces after the Korean War. The kind of psywar understood by the armed forces is a far narrower and more specialized operation than that to which scholars, journalists, and politicians refer when they say "psychological warfare."

As armies practise it, psywar involves the use of printing presses, radio stations, and air-dropped leaflets in pursuing goals of modern warfare. The term is also used to describe the pseudo-psychiatric twisting of personality by techniques such as "brainwashing" or "thought reconstruction" is the official Chinese Communist term) or the psychopharmaceutical techniques reportedly used in the European Communist countries. In this sense, the United States has not engaged in "psychological warfare." The only U.S. effort in the field has been developing preventives and countermeasures as far as possible. (See also BRAINWASHING.)

Finally, psychological warfare is loosely and often improperly used to describe all the forms of power struggle between nations: the "cold war," the "chronic war," "protracted struggle" (in Mao Tse-tung's phrase), "extended strategy," and the like. This is too broad a use for the term to remain meaningful. Marshall Plan expenditures, Mutual Security weapons deliveries, technical-aid programs—all of these have a psychological effect on the many audiences which make up the international scene, but their primary purpose is not the manipulation of opinion.

Modern psychological warfare is neither better nor worse than other forms of struggle. Insofar as it does the least damage to the human body, compared with other weapons, while achieving what may be maximum results in terms of cost, psywar may be regarded as a "better" weapon. A dead enemy is of no use to one's own side or to mankind, and his death may be very costly to achieve, while a live, surrendered enemy is usually useful.

Most psychological warfare material is truthful. Truth is easier to document than falsehood, and it is infinitely superior to lies where consistency is concerned. Lies were used wholesale in World War I; it is a safe guess that they were used less in World War II. Lies continue to be used in military conflict, but they are useful only in exceptional cases. The truth presented in psywar is rarely the whole truth, and the degree of veracity varies with the different countries engaged. During World War II the United States practice of covert psychological warfare, which presumably would be reactivated in the event of future conflict, was the responsibility of the Office of Strategic Services (OSS), while overt psychological warfare was reserved to the Army and Navy and the Office of War Information (OWI).

Overt or white propaganda is that emanating from a known source, while covert or black propaganda is issued from a falsified source. The British "German" transmitter, Gustav Siegfried Eins, which pretended to be inside the Hitlerian Reich, is a good example of black propaganda. Many Germans thought for a while that it really was German. In contrast, transmissions of the Domei (Japanese) news service in clear newspaper English to the U.S. during 1941-45 were a good example of white propaganda. Though admittedly Japanese, the dispatches filled a lot of U.S. newspaper space and embarrassed the U.S. war effort.

Strategic and Tactical Levels.—Apart from communications media, psychological warfare is sometimes divided into levels which reflect the frame of space and time in which the military propaganda is expected to operate. Strategic psychological warfare is the term denoting mass communications directed to a very large audience or over a considerable degree of territory. An appeal to the enemy civilian population to hoard food in order to protect their families against privation would be strategic in character. Tactical psychological warfare usually implies a direct connection with combat operations; the most common form is the surrender demand, although on other occasions tactical psywar may merely ask the enemy to retreat, tell individual soldiers to seek cover, warn city populations of bombing raids, or instruct civilians on how to behave if an airborne force suddenly lands among them. Consolidation psywar consists of messages distributed to the rear of one's own advancing forces for the sake of protecting the line of communications, establishing military government and carrying out the governmental tasks of the commanding general.

Surrender leaflet distributed to Japanese troops in the Philippines and other Pacific Islands during World War II. The first version of the leaflet carried the words "I surrender," which so shocked the Japanese that they would not use it

The same levels of distinction are sometimes made by use of the criterion of "action response." If an armed force or government uses psywar to prepare an audience for an action to be taken at an indefinite later time, the propaganda is called strategic; if a specific action is called for, it is termed tactical. Continuation of the "cold war" and the threat of "multipolar politics" arising from the admission of a great number of new states to the UN and the community of nations have accentuated the importance of multinational psychological operations in support of strategic security.

Intelligence Functions.—Two separate but equally important intelligence functions always accompany professionally managed psychological warfare. The

first and most obvious intelligence function consists of the analysis of one's own and the competing propagandas, together with the general flow of mass communications through the audience which is addressed. Sometimes particularly important decision-making parts of the audience, termed target groups, will be evaluated in detail. Who is reaching them and through what broadcasts or printed media? What do the audience members prefer? What do they repeat? The amount of communications in an enemy's propaganda to outsiders will often reveal his intentions; an enemy government's home broadcasts almost inevitably show what the enemy leaders think the opinions and problems of their own people are. This is called propaganda analysis; in military form, it is merely an adaptation of civilian methods of public-opinion analysis.

The second form of intelligence is no less important. It consists of audience information for the propagandist. The psywar operator cannot make effective use of persuasion unless he is given concrete details about his audience. In wartime much of this information comes through espionage channels and is therefore difficult to obtain. There is a natural conflict between espionage officials who wish to keep all incoming information secret and psywar officials who wish to use the realistic parts of it to strengthen their messages.

Media.—The communications media most commonly used in psychological warfare are the same as those used in civilian life; radio, newspapers, motion pictures, books, and magazines form a large part of the output. Leaflets are more widely used than they are in civilian life. (The World War II leaflet output of the Western Allies alone, excluding Russia, was at least 8,000,000,000 sheets.) Loud-speakers are often used in the front lines; both sides used them in the Korean fighting. The slow media are those in which a physical object must be transported to effect the communication: magazines, pamphlets, books, lecturers. The fast media are the telegraph and radio. The media used in a war usually reflect the capacity of the civilian economic system of each of the contestants. Whatever the medium, psywar can be successful only if it is credible, simple, and properly timed.

PSYCHOLOGISM, in philosophy, is the view that problems of epistemology (that is, problems relating to the validity of human knowledge) can be solved satisfactorily by the psychological study of the development of mental processes. Locke's *Essay Concerning Human Understanding* may be regarded as the classic of psychologism in this sense. A more moderate form of psychologism maintains only that psychology should be made the basis of other studies, especially of logic. A classic attack on both forms of psychologism is Edmund Husserl's *Logische Untersuchungen* ("Logical Investigations," 1900–01).

See John Passmore, *A Hundred Years of Philosophy* (1957).

PSYCHOLOGY (ARTICLES ON). The subject matter of psychology—the behaviour of people and other organisms—receives a general overview in **PSYCHOLOGY**, which surveys the scope and methods of the science, its major schools of thought, and fields of specialization.

PSYCHOLOGY, HISTORY OF, traces the evolution of psychological theories beginning with those of the ancient Egyptians. Prior to the 19th century the content of psychology was predominantly philosophical and introspective. The radical shift to the experimental and behaviouristic emphasis of psychology is reflected in articles on **BEHAVIOURISM**; and **PSYCHOLOGY, EXPERIMENTAL**.

PSYCHOANALYSIS is devoted primarily to theory; however, the reader who seeks a fuller view of modern psychological theories should consult, in addition, articles on **PSYCHOLOGY, ABNORMAL**; **ANIMAL BEHAVIOUR**; **EMOTION**; **GESTALT PSYCHOLOGY**; **INTELLIGENCE**; **LEARNING**; **MOTIVATION**; **PERCEPTION**; **PERSONALITY**; **PSYCHOLOGY, COMPARATIVE**; and **PSYCHOLOGY, PHYSIOLOGICAL**, among others. Much, if not most, of the disagreement among workers in psychology is with respect to theory and interpretation rather than with respect to the facts about behaviour.

Differences in interpretation are greatest in those areas where generally acceptable empirical evidence is limited. For example, active disputes continued in the 1960s concerning the effectiveness of **PSYCHOTHERAPY**; in this field where rigorous research is difficult, the limited number of empirical studies available indicated that such techniques yield no better results among disturbed people than are observed to occur in the absence of formal treatment. Disagreements continued concerning the validity of reports of paranormal activities as described in **PARAPSYCHOLOGY**; **PSYCHICAL RESEARCH**; and **SPIRITUALISM**.

The range of psychology extends from the biological (clearly, the behaving organism is a biological entity) to the social (behaviour, particularly in humans, can be influenced decisively by social determinants). Those interested in the biological basis of behaviour should also consult the articles on **BRAIN**; **ELECTROENCEPHALOGRAPHY**; **ENDOCRINE GLANDS**; **HEARING**; **MEDICINE AND SURGERY (ARTICLES ON)**; **NERVE**; **NERVOUS SYSTEM**; **NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY**; **PHYSIOLOGY**; **SMELL AND TASTE**; **VISION**; and **ZOOLOGY**. Similarly, **ANTHROPOLOGY**; **PSYCHOLOGY, SOCIAL**; and **SOCIOLOGY** give a view of the role of social factors in behaviour.

Many articles (for example, **CHILD PSYCHOLOGY**; **CONDITIONING**; **DREAM AND DREAMING**; **FEELING, PSYCHOLOGY OF**; **PSYCHIATRY**; **SEXUAL BEHAVIOUR**; **THINKING AND PROBLEM SOLVING**; **UNCONSCIOUS**) treat behaviour from both points of view because it is a function of interacting biological and social factors.

From its beginnings, scientific psychology has had strong interests in methodology and has developed a variety of techniques and apparatus for experimentation and analysis—on its own and by borrowing from other sciences. Some of the techniques and devices are primarily for laboratory use; others have been developed for the school situation, the clinic or hospital, and business and industry (**EDUCATIONAL PSYCHOLOGY**; **PSYCHOLOGY, APPLIED**; **PSYCHOLOGICAL TESTS AND MEASUREMENTS**; **PSYCHOPHYSICAL METHODS**; **SPEECH AND LANGUAGE**). Applied psychology is growing actively; new applications of basic psychological knowledge emerge continuously as techniques developed for laboratory use demonstrate practical utility (for example, **PROGRAMMED LEARNING**). The distinction between applied and pure science is often less clear and categorical in psychology than in some other fields. Thus, for example, analogies between electromechanical devices and living organisms as noted in **CONTROL SYSTEMS**; **CYBERNETICS**; and **SERVOMECHANISM** increasingly are attracting both theoretical and practical interest. (C. Ce.)

PSYCHOLOGY is a behavioural science that has primary reference to human beings acting alone and in groups. As such it impinges upon several other fields. It is possible to isolate for study living units at the levels of cell, organ, individual, group, and society. Physiology and neurophysiology are concerned with the functioning of cells and organs. Sociology studies the structure and function of groups and societies. Anthropology deals with the multiple cultural adjustments humans make to varied environments. Biology, economics, political science, and, in part history, philosophy, and theology all focus on problems related to those of psychology. While there are no clear-cut, universally accepted distinctions among the various disciplines, it can be said that the psychologist makes statements that describe behaviour in response to a variety of stimuli, turning to physiology and neurophysiology to demonstrate mechanisms by which the effects are produced. Also he deals with the individual mechanisms that underlie the group and social phenomena studied by the sociologist. In general, the psychologist is interested in the whole individual in his rela-

tion to his surroundings and himself. The question of whether psychology is a biological science or a social science has been a point of contention among some scholars. Depending on the major concerns of any given psychologist, the discipline has been classified in either way. In the 1960s, however, it was becoming increasingly common to hear psychology called a behavioural science. Not only are contemporary psychologists concerned with living beings; they also study the behaviour of such nonliving systems as electronic devices.

Because psychology is so inclusive, it necessarily encompasses numerous specialties. This diversity sometimes contributes to an appearance of disunity that is in turn increased by the lack of a theoretical structure acceptable to all psychologists. Thus there are clinical psychologists, experimental psychologists, physiological psychologists, comparative psychologists, industrial psychologists, and social psychologists, all of whom, after undergoing somewhat different training, follow separate specialties. The discipline finds unity, however, in a common interest in highly integrated organisms. It is difficult to discuss sensing without involving perceiving, perceiving separate from learning, learning without reasoning, or any of these processes apart from emotional and motivational aspects of behaviour. And it is difficult to isolate the organism from the external environment, where the immediate situation and past experiences are transparently significant.

Psychology began as a part of philosophy, and it was not until the late 19th century that it became a separate experimental science. A fundamental philosophical question is that of epistemology: What is the relation of experience to reality? The problem, recognized long before Plato, continues to arise in current discussions of consciousness. As their sciences developed, 19th-century physicists and physiologists became interested in whether psychological activities followed laws analogous to those describing, say, the behaviour of gases. Early experiments in psychophysics indicated a link between physiological and psychological activities. (See PSYCHOPHYSICAL METHODS; PSYCHOLOGY, HISTORY OF.)

"Pity poor psychology," it has been said. "First it lost its soul, then its mind, then consciousness, and now it's having trouble with behaviour." The lament is a summary statement of the way in which constructs that had served philosophers as explanatory concepts were successively discarded by some scientific psychologists as they moved from attempts to deal with the mind-body question, to consideration of conscious and unconscious processes, and finally to the insistence that behaviour alone is available for study by public science—that such constructs as "mind" either refer to non-existent or are irrelevant. In the second and third decades of the 20th century, behaviourism (*q.v.*) was embraced by many psychologists, especially in the U.S., who believed it would sweep away centuries of speculation and open the way for true science.

Behaviourism was challenged by Gestalt psychology (*q.v.*), a school which began in Austria and Germany and continued in the U.S. after Adolf Hitler rose to power. Gestaltists experimented with perceptual processes and emphasized the importance of the brain in organizing sensory data. They looked upon behaviour as taking place in a field of forces, and held that organized subjective experience is mirrored by a comparable isomorphic process in the brain. Modified forms of behaviouristic stimulus-response and Gestalt field theories still had proponents in the 1960s.

The historic concerns of philosophers with issues of human motivation, emotional behaviour, the bases of aesthetic choice, and ethical aspects of human nature are of major interest in scientific psychology. Sigmund Freud (*q.v.*) was not the first to note that many potent factors in human psychology operate below the level of awareness. (Socrates seems to have felt the same way.) However, Freud substantially influenced psychologists by developing a theory of unconscious determinants of behaviour and applying it to the care of psychologically disturbed people. Since the beginning of the 20th century Freud's work has had great scientific and cultural impact. See PSYCHOANALYSIS; UNCONSCIOUS.

THE METHODS OF PSYCHOLOGY

A few of the classical techniques in psychology can be listed here. These methods are in general similar to those of other sci-

ences, and frequently involve variables that are not available for direct manipulation and measurement. However, there are many observable activities that can be used to make inferences about psychological characteristics that defy direct measurement. While there seems to be no such physical entity as intelligence, for example, it is possible to measure the degree to which a person behaves intelligently in solving a number of problems (see INTELLIGENCE).

Statistical methods are among the most widely used tools in psychology. They permit masses of behavioural data to be studied efficiently and to be described succinctly. Such descriptive statistics as averages allow convenient comparison of different groups of individuals. Correlational statistics are used to describe relationships among psychological variables, as in assessing the efficiency of vocational interest test scores in predicting occupational success. The probability that psychological changes (*e.g.*, the effect of tranquilizing drugs on anxious patients) are significant rather than mere chance variations can be specified through statistical inference (see STATISTICS).

Direct observation with no effort made to control the behaviour under study is the simplest way to gather data. Careful noting of events taking place in a schoolroom, the keeping of a diary describing day-to-day changes in the behaviour of an infant, or the recording of group discussions are examples of this method.

The experimental method adds control over the observations and permits manipulation of behaviour. The method of co-twin control, for example, is used to distinguish genetic from environmental influences: identical twins raised apart may be studied to indicate what effects favourable and unfavourable environments have on measured intelligence. Foster children also have been used to study the problem, by comparing the child's performance on tests with those of his true parents and of the foster parents with whom he was raised (see PSYCHOLOGY, EXPERIMENTAL).

Special apparatus is used to teach people or other animals to make discriminations—say between a black and a white card or a right and left turn—by reward or punishment. Variations in performance are produced by the systematic introduction of changes in the experimental situation. Various problem boxes and mazes have been devised for the study of such functions as learning and reasoning.

Some aspects of emotional behaviour can be observed precisely. Facial expressions and gestures can be photographed. The psychogalvanometer (see PSYCHOGALVANIC REFLEX) records electrical changes in the body under stress. Breathing rates, blood pressure, pulse rate, and other bodily functions alter with emotional change, and are sometimes used in lie detection (see INVESTIGATION, CRIMINAL).

The method of introspection is used to get some idea of the conscious experiences of others. In such studies the subject reports his experience verbally or by pressing a key or performing some other act. Efforts have been made to give some rigour to this method; *e.g.*, by averaging repeated introspective observations to diminish the effects of incidental fluctuations in awareness of stimuli. Questionnaires of various sorts have been used in an introspective approach to the study of attitudes. If the person wants to hide his feelings, he may give inaccurate answers. Or he may be unable to communicate his introspections accurately. His actual behaviour, also, may differ sharply from his indicated attitudes, as is likely to be true in such matters as race relations and family relationships. Despite such difficulties, introspective data are widely and profitably used; without them, the scope of scientific psychology would be sharply curtailed.

Interviews in which the subject is encouraged to talk at length about his attitudes, guided by questions from the interviewer, can yield more detailed information than simple questionnaires and are increasingly used in surveys of public opinion. Unless the sample of people in the survey is representative, serious errors in prediction can arise. Such mistakes, for instance, have been made in election forecasts (see PUBLIC OPINION).

The clinical interview is usually designed to learn about the maladjusted person or to help him express his feelings and understand them. Hypnosis (*q.v.*) can help the patient remember for-

gotten experiences or aid him in overcoming undesirable habits or attitudes. In the techniques of controlled association the patient is asked to say the first thing he thinks of in response to a question or stimulus word, or he may be instructed to say everything that he thinks of (free association) during the interview period.

Psychometric tests sample behaviour to permit comparison of individuals on a relatively standardized basis (see **PSYCHOLOGICAL TESTS AND MEASUREMENTS**). These may be objectively scored tests, designed to measure specific traits or abilities; or projective tests, consisting of pictures, ink blots, lists of words, sentences, or other stimuli, designed primarily to elicit emotional or attitudinal behaviour that the more restrictive objective tests may miss. These techniques are employed widely in the diagnosis of psychological disorders and as aids in guidance.

Stress interviews and tests employing real-life situations are used in selecting personnel for special military duties or industrial assignments. These techniques are designed to provide sufficient realism and to aid in predicting behaviour under difficult conditions.

Play materials are used with children as projective devices (for instance, to see how the child treats dolls representing family members) or to facilitate expression of emotional behaviour in the treatment of disturbed youngsters. In therapy through role playing patients of all ages play parts along with other actors, usually other patients. Commonly, the action proceeds extemporaneously. See **PSYCHOTHERAPY**.

THE CONTENT OF PSYCHOLOGY

Input Processes.—The world impinges upon us through such input processes as seeing, hearing, smelling, tasting, touching, and the sensing of vibration and temperature change. Bodily changes are reported by pain, muscle, and joint experiences and what has been called the sense of balance or equilibrium. Of these the earliest to be studied scientifically and the most thoroughly understood are visual processes and hearing. Stimuli reaching the appropriate sense receptors are transmitted by peripheral nerves to the central nervous system. The nature of the receptors and of the neural transmission seems to dictate which sort of energies will be sensed and which will not. Stimuli must be of sufficient intensity to cross the limen or threshold of a sensory system or else people will seem to be unaware of them. Dogs and some other species seem to hear high-pitched sounds beyond the range of human hearing. There is mounting evidence that for normal function, the nervous system needs a constant minimal sensory input; otherwise people will tend to hallucinate and exhibit other abnormal behaviour. (See **SENSATION**.)

Central Processes.—*The Central Nervous System.*—(See **BRAIN**; **NERVE**; **NERVOUS SYSTEM**; **PSYCHOLOGY, COMPARATIVE**.) More complex animals tend to have large brains in proportion to body size and show encephalization, a tendency for higher nervous centres to mediate functions controlled by lower centres in less complex species. In humans even those vegetative functions mediated by the spinal cord and more primitive portions of the brain are represented in the cortex. The histology and neuroanatomy of the nervous system have been studied in detail and the activity of many areas is partially understood. The brain is known to be incessantly active throughout life, even in sleep. However, the function of much of the brain, including the frontal lobes, is poorly understood. Studies of other animals as well as brain-injured and surgically treated people have located brain areas whose damage permanently impairs or destroys such processes as seeing or speaking. The neural bases for learning, reasoning, and perceiving are not clear, and the meaning of such factors as attending, willing, and decision-making in terms of brain activity awaits further study. Electronic computers have been viewed as models of brain mechanisms and clearly seem to mimic some brain functions (see **CYBERNETICS**; **SERVOMECHANISM**).

In the 1960s split-brain studies were attracting increasing attention. Humans and laboratory animals in whom the nerve fibres that normally connect the two halves of the brain have been severed behave as though they have two brains. The individual seems to learn, perceive, and remember as if he were two independent in-

dividuals that can alternate from moment to moment (depending on which brain hemisphere is being used). In such cases the left hand literally does not appear to know what the right hand is doing.

Perceiving.—The process of meaningfully organizing sense data is called perceiving. Retinal images change shape and size as a stimulus object moves. Colours change with light and shadow as backgrounds alter. The observer, however, perceives that the steadily enlarging image of a car means that it is approaching; that the yellow of a lemon remains the same in sunlight or shadow; that the square has four right angles even though its image on his curved retina has none. He is able to recognize familiar songs in any key (see **PERCEPTION**).

Learning.—The central process of learning has been a major concern of psychologists since the earliest days of the science. By the 1960s there existed a formidable bulk of experimental data upon which to build theory and to base further research. It continued to grow as rapidly as scientific journals could print papers on the problem. Experiments on memorizing nonsense syllables, published in 1885, were among the earliest of these studies. They demonstrated that such material is acquired in an orderly way that, when plotted graphically, results in regular curves. Learning of meaningful material can produce such curves under certain conditions, but the process is more complex, being affected by the difficulty of the task, familiarity with its content, attitudes toward its meaning, and other factors. Motor habits such as operating a typewriter are learned in similar regular fashion.

Increasingly it has been possible to specify conditions that facilitate or inhibit learning. Active participation of a subject in an experiment, for instance, produces more rapid learning than when he merely listens passively as the material is read to him repeatedly. Motivational factors, such as expectation of reward or fear of punishment, also operate to influence the rate of acquisition of new information. Situations that produce pleasure or prevent pain tend to be learned and retained while those that produce pain or prevent pleasure tend to be forgotten. Up to a point increasing distraction operates to speed the rate of learning, but beyond that point the process is hampered. The set or attitude of the learner, his emotional reactions to the material, his motivations, social factors such as the presence and reactions of other learners, all affect the process (see **LEARNING**; **CONDITIONING**).

In some species a process known as imprinting takes place (see **ANIMAL BEHAVIOUR**) in which the first experiences have an immediate and lasting effect. It has been shown that a gosling will follow a human being who quacks at him during the first few minutes after hatching if the mother goose does not get there first. Thereafter the gosling will follow the human being in preference to the goose. According to some this effect is permanent, although this has been questioned by others.

In the 1960s it began to appear that in some species the effects of learning could be absorbed through the digestive tract. Untrained cannibalistic flatworms (*Planaria*) seemed to show the effects of training simply as a result of eating trained *Planaria*.

Remembering.—The retention of learned material was regarded classically as the maintenance of associations established in learning. However, as time passes the memory trace is modified. Experimenters have asked subjects to make successive drawings from memory of an outline picture of an owl. Typically such drawings progressively dropped out details, finally losing the characteristics of an owl and ending as the more familiar outline drawing of a cat. Apparently, remembering is subject to change as it is affected by prior experience and by later events. It had been found earlier that forgetting of nonsense syllables, like learning, followed a smooth curve—in this case a decay curve. Much research in remembering actually deals with forgetting. It has been found that to keep a conditioned response lively it must be reinforced from time to time. Also, extinction of the response can be hastened by presenting the conditioned stimulus without reward or punishment.

Events occurring after learning or conditioning can interfere with retention; this is called retroactive inhibition. Remembering is more efficient after sleep than after a comparable waking period, presumably because in sleep there are no interpolated tasks to in-

hibit remembering retroactively. Proactive inhibition also occurs, whereby later learning is prevented or altered by earlier events.

By hypnosis or free association people are able to remember long-forgotten events. It seems that in some way the brain retains impressions that are not always available to awareness (see MEMORY).

Problem-Solving.—Though thinking and reasoning are often held to be particularly characteristic of humans, the body of experimental material on them is relatively small and theory is primitive. About the turn of the 20th century the chief argument in this field centred around the question of whether thinking was characterized by a temporal chain of conscious images or could be carried on without such an association of images ("imageless thought").

Later controversy raged around the insistence that thinking is subvocal speaking; i.e., minimal activity of the laryngeal muscles. Some held that the solution of problems proceeds by random trial and error, the scope of trials becoming more delimited gradually as partial solutions are achieved. Problem-solving by laboratory animals has been studied in various kinds of problem boxes in which the animal receives a reward for completing the task. Multiple-choice apparatus has also been used to observe human problem-solving.

The Gestalt school made other assertions about problem-solving, stressing the instantaneousness of a solution as the conceptual field is restructured. They pointed to the surprise with which subjects suddenly see the answer, calling this the "aha experience." In experiments with difficult problems for which answers were not immediately apparent, solutions were reached by one or more restructurings of the problem.

In ways somewhat similar to the problem-solving process, the central process of decision-making has been increasingly investigated. In some region of the nervous system, many inputs from the environment and from other parts of the body must be resolved in order to give rise to a single output, or a limited number of them. In neurophysiological terms, a final common path must be selected. This is decision-making, and it is being increasingly investigated with the assistance of a special branch of mathematics related to the statistics of probability (see GAMES, THEORY OF; THINKING AND PROBLEM SOLVING).

Emotional Activities.—The experiences commonly called fear, rage, sorrow, and love are central reactions that involve visceral and emergency mechanisms of the body (see EMOTION). The autonomic nervous system, which controls functions like respiration, digestion, circulation, and glandular secretion, mediates various states of excitement and preparedness for action which characterize emotional behaviour. Digestion may stop, heart and respiration rates increase, adrenaline be excreted into the blood stream, and the blood sugar content be increased. Measures of blood pressure, breathing rate, blood sugar, and the psychogalvanic skin response, among others, have been used in experiments as indicators of emotional states.

Continued emotional stress, conscious or unconscious, is believed to have a role in many psychosomatic diseases, although the mechanisms by which these effects are produced are poorly understood. Disturbances such as schizophrenia have a profound effect not only on cognitive processes but also on the emotional state of the patient, characteristically producing apathy. Manic-depressive psychosis results in either excited or depressed emotional states or cyclical alterations between the two.

Anxiety has been given many definitions and explanations by experimentalists and clinicians. It is most commonly considered a subjective state of apprehension about a potentially harmful input from the environment. Anxiety neuroses are moderately severe emotional disturbances that may be associated with sweating, trembling, palpitation, and other autonomic responses (see PSYCHOLOGY, ABNORMAL; PSYCHIATRY).

Personality.—In an effort to unify their findings under a single rubric, many psychologists like to use the word personality. Definitions of personality are legion; however, the fashionable tendency in the 1960s was to consider personality as some sort of unique and relatively enduring organization of an individual's characteristics (see PERSONALITY).

Output Processes.—The output of the organism, aside from secretions and excretions, is produced through the effector system of motor nerves and muscles. All responses from the reflex knee jerk to the most complex verbal communication are included. Work output has been investigated experimentally. Time and motion studies, studies of conditions favouring and interfering with working efficiency, studies of optimum length of work periods have become usual in industrial psychology. All concern aspects of motor output. The finger ergograph, a device that records the performance of the finger muscles in pulling a weight, has been used in research on fatigue. Other devices, such as treadmills, have been employed to study larger muscle action. The resulting work curves show a characteristic rise in output as the muscles first warm up and then a decline with fatigue. The effects of rest pauses, interpolated activity, various drugs, and different motivations have been studied by these means. Fatigue in industrial settings, however, depends upon more complex factors than the ability of muscles to do work. Boredom, the feeling of tiredness which may precede real fatigue, variations in motivation, changes in morale—all alter output. Change of task, even though the same muscles are still used, for instance, may result in improved output. The effects of distraction upon work are complicated. Some distracting sound seems to improve performance, but overly intense, prolonged, or unpleasant distraction, noise, or confusion reduces output significantly. (See PSYCHOLOGY, APPLIED.)

Speaking is another sort of output. The neural and muscular mechanisms of verbal behaviour, its efficiency, and pathology in such conditions as stuttering and aphasia are being increasingly investigated. Information theory (*q.v.*), derived from physics, is providing concepts and measuring units for research on communication among people and machines. Historically there has been a tendency to minimize the output activity of the organism, with primary emphasis on input and central processes. Much of the work in output processes is recent (see COMMUNICATION; SPEECH DISORDERS; PSYCHOLOGY, SOCIAL).

Developmental History.—The study of the development of organisms from the embryo to old age is called the longitudinal approach. Studies of human embryonic and infant motor development indicate that the earliest movements are uncoordinated, involving the whole body. Reflexes such as the sucking response and the Babinski sign (fanning upward of the toes when the sole of the foot is scratched) are present in human infants at birth. Controlled voluntary actions begin to develop within the first weeks of life, as the nervous system matures, proceeding in general from the head downward (see CHILD PSYCHOLOGY).

As the number of older people in the population increases, growing interest is being shown by psychologists in the process of aging. Although this surge of interest is a relatively recent development, the effort has begun to bear fruit. For example, reports in the 1960s indicated that ribonucleic acid (RNA), a substance prepared from proteins, acts to ameliorate memory deficit when administered to senile people (see GERONTOLOGY AND GERIATRICS).

PSYCHOLOGY, ABNORMAL, the study of morbid deviations from normal behaviour. Under the term behaviour is included such functions as motivation, perception (*qq.v.*), imagination, thinking, and memory (*q.v.*). Abnormal behaviour is classified under the psychoneuroses, psychoses, and psychosomatic disorders, the personality and sociopathic disorders, and the disturbances occurring in intoxications, brain damage, and brain disease.

The overwhelming and ever increasing evidence for the involvement of physiological factors in the development of abnormal behaviour is considered in many articles including ALCOHOLISM;

CEREBRAL PALSY; DELIRIUM; ENCEPHALITIS; EPILEPSY; GENETICS, HUMAN; HYDROCEPHALUS; MENTAL DEFICIENCY; PSYCHOLOGY, PHYSIOLOGICAL; SPEECH DISORDERS; STROKE. The vast majority of psychologists in Great Britain and the United States have no medical training and yield to physicians whenever measures involving physical diagnosis, surgery, or drugs are involved in dealing with these disorders among human beings (see DIAGNOSIS; DRUG ADDICTION; NERVOUS SYSTEM, SURGERY OF).

In considering abnormal behaviour among people, psychologists often work in close association with physicians, and tend to limit themselves to so-called psychological methods (e.g., see PSYCHOTHERAPY). In the face of their limitations, some psychologists are especially prone to stress those approaches to abnormal behaviour that require no competence in physical medicine, as do some physicians who are psychiatrists. Thus, much effort among specialists in abnormal psychology is directed toward understanding social-experiential-psychodynamic factors (e.g., see PSYCHOANALYSIS). These considerations receive primary attention in the discussion to follow.

Certain basic phenomena, not in themselves pathological, are dealt with extensively in abnormal psychology because of the central role they play in abnormal behaviour. Among these are anxiety and the defense mechanisms used to control it; unconscious motivation and drives; conscious, preconscious, and unconscious processes; and the part played by frustration and conflict in precipitating and maintaining abnormal behaviour. In addition, it is customary to include the study of normal dreaming and hypnosis, as well as such normally occurring phenomena as hallucinations and delusions. Much attention has been focused upon the effects of extreme deprivation, found among concentration camp victims and hospitalized infants, and, under experimental conditions, among volunteer subjects isolated from normal sensory stimulation.

This article is organized as follows:

- I. Normal and Abnormal
- II. Development of Abnormal Psychology
- III. Origins of Psychopathological Symptoms
 - A. Early Childhood
 1. The Mother
 2. Identification
 3. Rivalry
 4. Maturation Sequence
 - B. Development of Ego, Id, and Superego
 1. Ego

 - C. Psychotic Reactions
 1. Paranoid Reaction
 2. Schizophrenic Reactions
 3. Affective Reactions
 4. Brain Disorders

I. NORMAL AND ABNORMAL

A distinction between normal and abnormal behaviour is of considerable practical importance not only in psychology and medicine but in all studies of social interaction among individuals, groups, social classes, communities, and nations. Problems of communication, for example, are fundamental to all social interaction. These problems cannot be met effectively without knowledge of the distortions of perception, interpretation, and decision which personal factors introduce, many of them lying close to or within the borders of the psychopathological. The legal profession is beginning to revise some of its fundamental conceptions of crime,

responsibility, and punishment in the light of modern knowledge of normal and abnormal motivation.

Unfortunately, it is extremely difficult to work out a definition of normal behaviour that is generally acceptable—far more difficult than to define normal business conditions or normal weather. People typically tend to consider themselves as the standard of normality and to regard as signs of abnormality any actions, attitudes, or experiences of other people that differ markedly from their own. Such a criterion, however, is not always acceptable to others. Millions of people who are diagnosed as neurotic and psychotic may consider themselves normal; at any rate, everyone at some time or other acts or thinks a bit strangely.

An alternative is to judge each person's behaviour in relation to that of others in his community who are of the same sex, belong to the same age group, and live under similar socioeconomic conditions. To make such judgments a system of well-defined norms is needed with which any given sample of behaviour may be compared. However, obstacles to the use of rigidly specified behaviour norms include: the heterogeneous composition of contemporary industrial society; the increasing social mobility of individuals and groups, which increases cultural conflict; the rapid changes in accepted standards of behaviour; and the slow rate at which knowledge concerning human motivation has been assimilated into major social institutions.

Because of these difficulties, and the existing limitations in available techniques, a strict differentiation between normal and abnormal remains to be made. A rough working criterion of normality is the relative adequacy of a person's behaviour as judged in comparison with the behaviour of other persons who share his status in his society. Such a criterion is in some degree subjective; indeed, it is not unusual for authorities to disagree in their judgments of normality. However, it faces the fact of a relatively wide range of culturally acceptable behaviour.

It is important to recognize that, in this context, adequacy of behaviour is not necessarily the same as work efficiency or social conformity. Efficient work sometimes involves the compulsive exploitation of oneself or of others, and may stem from a deviant need to display personal power, to punish oneself, or to eliminate irresistible temptation by eliminating one's leisure. Likewise, social conformity is not always a sign of health. Sometimes it expresses extreme social timidity or fear of one's own antisocial impulses. In short, behavioural adequacy as a mark of relative normality must be viewed not only from the point of view of an outside observer but from the point of view of the behavior as well.

With this dual orientation, behaviour may be called abnormal under the following conditions: (1) if a person, otherwise in good health, shows himself incapable of establishing and maintaining mutually satisfying interpersonal relationships; (2) if his behaviour, including perception and thinking, is or becomes strikingly inappropriate in terms of prevailing social norms; (3) if, to carry on ordinary activities, a person is obliged to expend disproportionate effort, in comparison with others of his own age, physique, intelligence, and training; (4) if he is unable to obtain satisfaction from his activities, his memories, and his prospects; (5) if he experiences chronic lack of feeling, sense of isolation, or emotional instability; (6) if he suffers from high levels of tension, anxiety, or conflict for prolonged periods, or must defend against such suffering through pathological symptom formation.

It should be understood that relatively normal people are expected to exhibit some disturbance in sterile or stressful circumstances. For example, a person whose occupation is unchallenging or too demanding is expected to respond with dissatisfaction; refugees among people whose language they cannot speak, or individuals living with others who share few interests or values, typically experience anxiety or a sense of isolation. Thus, any criteria of abnormality (including those given above) must be applied with caution, giving full consideration to the situation in which the person is placed.

II. DEVELOPMENT OF ABNORMAL PSYCHOLOGY

Mankind has shown profound concern over abnormal behaviour from ancient times. Attempts to account for the phenomena of

abnormal psychology have varied all the way from ascribing them to demoniac possession and loss of the mind or soul to blaming them upon hereditary taint and organic disease, usually of the brain but by no means invariably so. Galen, for example, ascribed hysteria to malfunction of the ovaries; the medieval philosophers related melancholia to an excess of black bile, which the word actually means.

Treatment through the ages has fluctuated irregularly over a correspondingly wide range, especially with respect to insanity. At one extreme are found drastic medical and surgical interventions; purging and bleeding were extensively used. At the other extreme are found the use of incantation and exhortation, of flogging and cold-water shock, and for centuries the use of capital punishment, as in the worldwide witch prosecutions.

The emotional origins of abnormal behaviour and the crucial part often played by interpersonal relationships have been implicitly or explicitly recognized for millenniums. But it remained for Franz Anton Mesmer (*q.v.*) to demonstrate, consistently and on a large scale, that emotional crises and pathological symptoms can be deliberately induced and cleared up through the influence of one person upon another. He thus ushered in the modern era of psychopathology.

Because of the tempest of controversy that followed Mesmer's activities, his methods were shunned by reputable persons, and for a long time his positive contributions were overlooked. A gradual revival of mesmerism, renamed hypnotism, developed during the middle third of the 19th century and led to a second public controversy. This time it was between J. M. Charcot (*q.v.*), the great neurologist in Paris, and H. Bernheim, professor of medicine in Nancy. Charcot maintained that only the potentially hysterical could be successfully hypnotized, while Bernheim insisted that anyone could be. Each was partly right; it is known today that most adults can be hypnotized, and that many hysterical symptoms can be hypnotically induced in apparently normal people. By far the most important outcome of this celebrated quarrel, however, was a greatly increased interest in the nature and characteristics of psychopathology. (See also HYPNOSIS; PSYCHIATRY.)

Pierre Janet (*q.v.*), who succeeded Charcot, began a series of contributions to abnormal psychology in 1889, devoting his attention first to obsessions and then to hysteria. His early writings have some of the germs of modern psychodynamics and his later clinical descriptions were brilliantly clear. The systems of diagnostic nomenclature used in abnormal psychology and psychiatry in the 1960s stem largely from the work of Emil Kraepelin (*q.v.*).

Sigmund Freud (*q.v.*) spent the year 1885 in Charcot's clinic while Janet was there, but he also looked into the other side of the controversy by visiting Bernheim in Nancy for a few months in 1889. He translated the writings of both Charcot and Bernheim into German soon after his visits. Unlike Mesmer, Freud shunned public controversy; worked with the utmost self-critical care, for many years almost in isolation, and met the condemnation of others largely by piling up considerable amounts of clinical evidence. Unlike Janet, he ranged over the whole field of psychopathology and invaded normal psychology as well, and his theoretical contributions were daring and revolutionary. In his *History of Experimental Psychology* (1950), E. G. Boring lists Freud as one of the "four very great men in psychology's history." Certainly no one else has influenced the development of abnormal psychology so profoundly and extensively as Freud. (For an evaluation of the related but divergent views of Alfred Adler, Erich Fromm, Karen Horney, Carl Jung, Otto Rank, and H. S. Sullivan; see R. L. Munroe, *Schools of Psychoanalytic Thought*, 1955.)

III. ORIGINS OF PSYCHOPATHOLOGICAL SYMPTOMS

A. EARLY CHILDHOOD

At birth the infant is separated physiologically from his mother, but for years he remains dependent upon her, or upon her substitute, for his very existence from day to day. His interrelationship with the mother figure is a most important factor in his earliest cycles of need and satisfaction, in his earliest experiences

of security and anxiety, in the comforting and disturbing aspects of bodily care, in his development of love and hate, in what he learns to expect from the world around him and how he learns to handle it.

1. The Mother.—Even the child's differentiation of his own body from his surroundings, and of himself from other people, depends upon a healthy maturing of the mother-child relationship. At first the relationship is normally symbiotic, that is, one in which the mother and child form an interdependent unit, each individual being of great importance to the other. There is much clinical and observational evidence to suggest that the infant in a symbiotic relationship does not distinguish between his mother, or her substitute, and himself. He makes such a distinction slowly, over a long period, by means of the normal maturing and use of his equipment for independent action. Under ordinary conditions this process of growing independence and differentiation goes on progressively and at an accelerating rate, especially with the development of walking and talking.

Whatever interferes with the gradual evolution from a symbiotic relationship to one of eventual independence may lay the groundwork for abnormal behaviour later on. An obvious source of difficulty is a mother's inability to give up her child's dependence because of the personal satisfactions she derives from it or because of the anxiety aroused in her by the child's attempts at independent activity.

Such a mother is often called overprotective. Her protection may take the form of overindulgence, which tends to leave a child always infantile in what he expects and demands, even after he grows to adulthood; or it may take the form of domination, which prevents him from developing initiative and enterprise. In either case, he is likely to remain a dependent person; even in adulthood, either expecting privileged treatment without earning it, or looking continually for guidance and approval from everyone. Needless to say, the presence of a strong father and of siblings in the home can offset to a considerable degree the stunting effects of maternal overprotection.

A less obvious but no less fruitful source of difficulty lies in an unsatisfactory symbiotic relationship, particularly one which fails to foster infant trust. This may be the result of maternal coldness or resentment toward the child. In may come from mothering which is carried on with unusual tension and anxiety, or from mothering that is grossly inconsistent and unpredictable. It may also develop because the child has behavioural characteristics, whatever their cause, which make him an unwelcome or uneasy partner for his mother. Apparently if an infant for any reason cannot enjoy a satisfactory symbiotic relationship when he is helpless he may not later develop into a satisfactorily independent person, for if he does not experience a high degree of infant trust he will be less equipped later to experience the basic trust in others which is the foundation of normal emotional relationships. He is likely to grow into a lonely, emotionally withdrawn, or suspicious adult.

2. Identification.—One of the most important means whereby a growing child develops psychologically is called the process of identification. Unlike the simpler forms of learning and problem solving, this process involves idealizing the behaviour of other people on a large scale and becoming in some important respects like them. Early in life identification seems to be relatively massive, rapid, and indiscriminate, but also relatively unstable. It occurs in relation to members of the family with whom the child is in close contact. As time goes on identification grows less complete, slower, and more discriminating, as well as more stable. The child takes over certain aspects of the people around him and ignores or rejects other aspects (partial identifications). Eventually the process of identification leads to a recognizable patterning of child personality, and this patterning influences not only what the child is like but also the direction of his further identifications and therefore of his ultimate character structure.

It is a peculiarity of personality organization that the effects of early processes seem never to be wholly lost. The earliest wholesale identifications may be profoundly modified by later experience; and many shifts in the general direction of identifica-

tions may occur during maturation. But in a crisis some of the apparently lost infantile patterns may reappear; this reappearance is what is called regression. This is especially true of the deep and massive regressions seen among psychoses, but it is also responsible for many psychoneurotic symptoms in which regression is more limited in scope and less deep. Failure to establish adequate stable identifications, because of defective parental relationships or the absence of basic security, is held to be especially important in sociopathic personality disturbances.

3. Rivalry.—Rivalry is a very frequent element in family living. Living together means sharing; and sharing means giving something up as well as getting something. The birth of a sibling is an almost unailing source of rivalry for a first child, and a common source for any child. Not only may it provoke anger and a sense of being unloved in the older one, but it also may lead him to retaliative aggressions which disturb the development of the younger one. Such retaliations at first may be quite open and direct, but in the face of parental disapproval they become disguised and indirect, although still effective. Most children survive the common experiences of rivalry without noticeable harm. The lives of many adults, however, are overshadowed by excessive competition, envy, and jealousy, or by reactive inability to compete and to be envious, which often seem to have their roots in unmastered sibling rivalry.

A small child's rivalry with one parent for the love of the other is potentially the most serious interpersonal conflict in early life. The mere intensity of his own feelings, and the tremendous size and power of his adversary, can conjure up a situation of unreal but frightening danger. And this kind of conflict is further complicated by the fact that, as a rule, the child also loves his rival parent and needs his rival's love. The eventual resolution of this problem is at best slow and painful. Out of it comes the mature form of the normal superego and a newfound freedom for the child to turn with self-confidence to active mastery of the world of people outside the home. Failure to resolve the conflict optimally can be found in a majority of persons showing abnormal behaviour.

4. Maturation Sequence.—A final point of importance is the factor of maturational sequences. Success in any phase of childhood development is in part dependent upon success in preceding phases. A boy, for example, who remains too long in a symbiotic relationship with his mother may lose early opportunities for handling rivalry with his siblings and for resolving rivalry with his father. He begins late, and with less than optimal freedom, to develop initiative in adapting to his environment and mastering its problems.

Moreover, a child who is insufficiently emancipated from close infantile ties with a parent is not free to take advantage of close friendships and group ties as these become available outside the home when he is six or seven. These relationships are critical for his development into a socially adequate person who is capable of mature emotional experience. A child who does not enjoy these maturing relationships will be poorly equipped to enter the turbulent period of adolescence and work out his self-identity in early adulthood. It must be said, however, that a good start does not guarantee freedom from serious difficulty in later emotional maturation; on the other hand, it is possible to overcome the handicaps of a bad start if a later phase of development provides unusually favourable conditions.

B. DEVELOPMENT OF EGO, ID, AND SUPEREGO

On the basis of Freud's psychoanalytic theories it has sometimes been assumed that during early childhood certain groupings of psychological functions are differentiated into permanent, organized systems called ego, id, and superego.

1. Ego.—The earliest differentiation is held to be between id and ego. This differentiation begins with the infant's earliest exploration, through which he learns to distinguish between his own body and his surroundings. Ego functions may be considered as those involved in what is called reality contact.

The ego-adaptive functions, which come to include the maturing perceptual, motor, and glandular coordinations, lead to more and

more effective performance in relation to the environment. The adaptive ego is said to become organized, during this process, in such a way as to make possible the complex kinds of interpersonal feeling, action, imagination, remembering, and thinking that characterize human beings. Most ego adaptations are held to function automatically and unconsciously in the mature adult. Processes of childhood identification, mentioned above, make indispensable contributions to ego organization. They lay the groundwork for the eventual internalization of culture and for the evolution of social attitudes, value orientations, role taking, and self-identity (see Ego).

2. Id.—The id is thought to involve primitive, loosely organized and potentially disruptive psychological activities. Such impulses push forward constantly for immediate discharge or gratification, without regard for the demands of external reality. Id is completely unconscious in the adult. Its existence and its modes of operation are inferred from certain peculiarities appearing in preconscious and conscious activities, such as the puzzling characteristics of manifest dreams, of slips of the tongue and of wit, the nature of symptom formation in neuroses, and of delusion and hallucination in psychoses. Id activities perpetually tend toward immediate discharge or gratification, even during sleep.

3. Superego.—The superego is said to reach the climax of its differentiation from the ego during the third to fifth year of life. Its familiar conscious form is called conscience. This is experienced as a part of awareness that at times criticizes, reproaches, or condemns us, and at other times seems to approve, justify, or praise us. According to some theorists the personality has a permanent split at unconscious levels into an evaluating system, which praises or blames, comforts or threatens (superego), and an evaluated system which receives the praise, blame, comfort, or threat (ego).

The superego is considered largely unconscious. In normal adults it is held less responsive to current reality factors than is the ego. A great deal of superego activity is primitive and irrational; the system is believed to crystallize during the first three to five years, in relation to powerful infantile emotional conflicts and long before logic or realistic thinking evolve. Evidence of primitive superego magic is said to be seen in obsessive-compulsive symptoms. The clearest evidence for irrational, infantile superego function, however, is said by some theorists to appear in depression and in mania, the one expressing consciously the most cruel and hateful attitudes toward the self and the other expressing extravagantly unrealistic self-adulation and self-will.

The general effect of superego development is to increase psychological stability. In organizing such a system the child acquires his own internal moral control. He can regulate his own behaviour without having to watch his parents continually to see if he is right. He builds up his own standards and ideals which he can carry with him wherever he goes. The superego is also considered a potent source of conflict. Even unconscious fantasies are held to stimulate the superego to arouse unconscious guilt. This is said to be seen in the gnawing sense of inferiority that troubles many neurotics and in the fantasies which make up delusions and hallucinations.

4. Interdependence.—According to psychoanalytic theory impulses and fantasies derived from the id are modified and channeled by ego functions into realistic thought and action, into daydreams, make-believe, and recreation. Interaction with superego functioning is said to provide value orientations and moral qualities for action, thought, daydream, and play. The theory that most of the interaction among these systems is unconscious and preconscious reflects the idea that much human activity cannot be accounted for on the basis of strict conscious rationality, that it has meanings that are not realized at the time.

C. CONSCIOUS, PRECONSCIOUS, AND UNCONSCIOUS

Among many psychologists three levels of activity are distinguished: conscious, preconscious, and unconscious. The conscious level includes whatever a person is aware of at a given moment and is said to constitute only a small fraction of mental activity.

1. Unconscious.—The unconscious theoretically includes all id

activity, most of the ego-defensive organization, and the greater part of superego functioning. Its purest form is said to be in id activity; some evidence of unconscious id, ego, and superego functioning comes from the study of manifest dreams, with their related feelings, fantasies, and thoughts, which find expression during free association (*see* ASSOCIATION, MENTAL). Usually the person who is freely associating does not recognize the evidence of unconscious processes in what he is saying, but a person trained in observation often can appear to do so. Psychotic symptoms are sometimes interpreted as reflecting unconscious thinking and feeling more or less unchanged. Neurotic symptoms, on the other hand, are as a rule more realistically adaptive, so that their unconscious origins may be, and remain, obscure for a long time, even during intensive therapy.

2. Preconscious.—The simple form of preconscious consists of all mental activity which is not conscious at a given moment but can easily become conscious by a shift of attention. Its organization is presumably the same while it remains out of conscious awareness as when it becomes conscious. There are said to be other preconscious processes that can become conscious only with considerable effort. These include relatively well-organized daydreams whose material contradicts present reality and manifest dreams which, although they reflect unconscious processes, can be experienced consciously and can be described in words to someone else. It is impossible to make sharp distinctions among conscious, preconscious, and unconscious.

D. NEED, DRIVE, AND MOTIVATION

While it is generally agreed that need is a basic factor in determining behaviour, there is still confusion over the use of the term. Some experts, for example, speak of need and drive as though the two were synonymous, but most show a strong preference for one term and slight or neglect the other. There is actually a difference in emphasis involved. Need stresses what is wanted (*e.g.*, need for food, for love, for mother), whereas drive stresses an internal force or push which seeks an outlet. There is also some lack of agreement as to the number of basic needs or drives, which varies in psychological literature from one to a dozen.

Those who take a psychoanalytic approach to abnormal psychology show a preference for the concept of drive (also called instinct) as the most fundamental. This view may be summarized as follows: there are basic drives, sexual and aggressive, whose derivatives impinge upon the unconscious ego through activities of the id. In controlling, channeling, and discharging these drive derivatives, the ego develops its complex system of defense mechanisms which modify the drive derivatives before these reach the preconscious or emerge in consciousness. The ego at the same time develops adaptive organizations in relation to external reality and, later on, in relation to superego functions also. This ego organization of drives in relation to reality and the superego leads eventually to the formation of complex systems of motivation which have their own hierarchies; *e.g.*, a man's love of country may take precedence over love for his children, whereas a woman's love of her children may reign supreme.

The factor of unconscious motivation is of prime importance in abnormal psychology. As long as life goes reasonably well, it need not be of great significance that a person does not really know why he does many things or has certain fixed attitudes, that he sometimes feels pushed to do unreasonable things and avoids doing reasonable ones, or that his troubles seem always to follow the same general pattern no matter where he is. If, however, life goes badly, if a person's actions grow unmanageable or his satisfactions are overshadowed by anxiety, doubts, or gloom, the unconscious origins of his behaviour can become of major importance. It should be said, however, that contrary to a widely held public opinion, many psychotherapists do not try to make all unconscious motivation conscious to the patient. Often it is best kept unconscious. *See* also INSTINCT.

E. EGO DEFENSE AND ANXIETY

Most ego defenses are seen as related to the control of anxiety, which an adult may experience in two major forms. The more

primitive form, called traumatic anxiety, is that of feeling in danger of imminent destruction. The less primitive, called signal anxiety, is in effect an anticipation of such danger, experienced in a much attenuated degree.

1. Traumatic Anxiety.—Traumatic anxiety is what an adult may experience when he is overwhelmed by a sudden catastrophe for which he is wholly unprepared. His response may be panic and headlong flight, a violent reckless assault, or a sudden trance state in which he wanders aimlessly about or becomes paralyzed and mute. Dramatic examples of such responses were reported from the battlefields of many wars; and in civilian life similarly violent and often maladaptive behaviour may be seen, for example, in theatre or school fires. Traumatic anxiety is especially common when flight and attack are both impossible, as when a soldier is isolated and pinned down in extreme danger by enemy fire.

Traumatic anxiety also is experienced when id derivatives break through ego defenses and threaten to disorganize ego function. This occurs in normal and neurotic persons during sleep if for any reason id derivatives threaten a breakthrough and produce a night terror from which the frightened sleeper is glad to awake. It also occurs in psychoses when a defective ego organization proves incapable of coping with direct id derivatives. Acute psychotic episodes sometimes include panic reactions like those seen on the battlefield and in fires.

2. Signal Anxiety.—Signal anxiety is a relatively mild experience of impending danger. If its source seems outside, the anxious person becomes vigilant, cautious, and defensive. If there seems to be no source, he feels uneasy, tense, and anxious without being able to understand why. In most neurotic and psychotic disturbances there is at least some feeling of an external source of anxiety. Much more commonly, however, the basis for the anxiety remains chiefly unconscious, and the threat comes from inner processes. The immediate automatic result is to increase ego defensive action, which also takes place at unconscious levels.

Increases and shifts in ego defense, as a result of signal anxiety, are assumed to occur automatically throughout the 24 hours of every normal person's daily life. What defensive pattern prevails at any moment, and what the commonest changes in ego defense shall be, depends upon the internal economy of the person, upon his personality structure, and upon the nature of the experienced threat. *See* DEFENSE MECHANISMS.

F. FRUSTRATION, REGRESSION, AND SYMPTOM FORMATION

1. Frustration.—Abnormalities of behaviour are usually precipitated by a series of frustrations. Frustration is experience of strong need accompanied by a sense of being prevented from satisfying it. What prevents satisfaction may be (1) an external obstacle—physical, social, or personal; (2) an internal conflict, conscious or unconscious; or (3) the absence of facilities for satisfaction, in the environment or in oneself. These factors of course can be understood only in relation to each individual person. Though some obstacles, conflicts, and lack of facilities affect everyone, even these affect different persons to different degrees. What seems an insuperable and intolerable obstacle to one person does not seem insuperable to another, or else does not seem especially important to him. Conflict and lack of facilities likewise are tolerated differently.

Additional variables are the strength of the drive and the character of the need involved. A frustrated powerful drive, especially one that is not successfully warded off by unconscious defenses, is more likely to precipitate a disturbance than a frustrated weak or well-defended one. Also, a need that involves too much physical, social, or psychological danger is almost sure to be frustrating, because each attempt to satisfy it will arouse intolerable anxiety. The closer one comes to its satisfaction the more intense the anxiety grows, and the less possible it becomes actually to achieve satisfaction.

Two of the commonest normal responses to frustration are aggression and withdrawal; *i.e.*, fight and flight. The aggression may be directed against the frustrating obstacle or it may be directed against a substitute, as when a person shouts at his child after he has been humiliated by his employer, whom he fears. The

withdrawal may be in the form of physical retreat or merely of passive withdrawal of interest. This last is the most important in abnormal psychology, because it is the most likely to result in regressive fantasy and symptom formation.

2. Regression.—Passive withdrawal of interest is not in itself pathological. When a normal person is bored, or when he is in a relaxed state before going to sleep, he automatically loses interest and turns to daydreams and fantasies. These imaginings are usually less realistic than are his thoughts about what he plans to do or remembers doing when he is more alert. It is not difficult to demonstrate that unconscious processes play a large part in such normal daydreaming and fantasizing. Anyone who examines his thoughts immediately after he has been deeply preoccupied or dozing will find some elements that certainly do not belong to his ordinary logical thinking.

This lowering of the level of functioning, from more to less realistic, is called regression. It is a movement away from logically ordered thought toward more primitive forms. An effective contact with reality and processes of logical thinking tends to prevent the appearance of such primitive functions, although these latter seem always to be potentially present.

During sleep dreams appear which are obviously regressive. They seem unintelligible afterward, and are a reflection of regressive unconscious logic. Wishes, fears, and conflicts that are expressed in dreams often surprise or shock the dreamer when he awakens and make him feel that he has been wandering in strange places with a different kind of reality and different moral codes. Nevertheless, it is usual for manifest dreams to exhibit some degree of superego function and ego defense, as well as to reflect raw id impulses and their fantasy derivatives.

3. Symptom Formation.—Symptom formation in neuroses is held to result from processes much like those resulting in a manifest dream, but the neurotic person withdraws a part of his interest in objective reality to escape frustration while he is awake, and not merely to enable him to go to sleep. In neuroses this withdrawal is never total as it is in sleeping and in some psychoses. A more or less effectual contact with external reality is always maintained. Likewise, regression is neither so sweeping nor so profound as that in normal dreaming and in psychoses. Usually a neurosis is precipitated not by one frustrating experience but by a long series of them, each leading to some withdrawal and partial regression. Eventually the succession of withdrawals and regressions leads to the reactivation of a primitive conflict whose origin lies in early childhood. This reactivated conflict now tends toward becoming conscious.

As in dreaming, so in neurotic symptom formation the superego and the unconscious ego defenses are believed active. The id impulses and derived fantasies, said to help make the reactivated conflict, do not erupt in their naked, primitive forms. They are subjected to defensive transformations more radical than most of those suffered by manifest dreams and, since the adaptive ego is wide awake and most of it attuned to external reality, the erupting impulses are subjected to further transformation until they harmonize more or less with reality. Thus a phobia based on an irrational childhood fear of one's father can be transmuted into an adult fear of dogs which the adult finds easy to rationalize and accept. It is only when, during therapy, a frightening father figure appears in a dream or free association reveals a still more direct relationship that the substitution may be suspected. (See also NEUROSES.)

Symptom formation in psychoses is held similar to the process in neuroses. A major difference is that ego organization is fundamentally unstable. Defects in ego adaptation are theorized to stem largely from defective early identifications and from early interference with the development of reality testing and initiative. Defects in ego defense consist mainly in the overuse of such primitive defenses as denial, projection, and introjection in situations which normal persons would handle through repression. A succession of frustrations, or sometimes a single severe frustration, leads to massive withdrawal from reality and sweeping regression.

The functioning that emerges in psychosis typically involves delusions and hallucinations that seem to be attempts to rebuild

external reality. The reconstructed reality seems made to correspond to primitive id, ego, and superego activities which have become conscious with relatively little defensive and adaptive transformation.

In this may be seen one respect in which a psychotic solution may be quite different from a neurotic one. Whereas the neurotic transforms his emerging conflicts adaptively, to make them conform as much as possible to external reality, the psychotic tends to transform reality, by delusion and hallucination, to make it conform to his emerging conflicts. The relative ineffectuality of ego defense and ego adaptation in psychoses renders it difficult to make an extensive transformation of unconscious material before it erupts into consciousness.

G. INDIVIDUAL SUSCEPTIBILITY

Sex differences, physiological age, and relative biological competence, especially of the brain, may all enter into determination of psychopathology. When it comes to individual differences in susceptibility, these physiological factors seem to be reflected in differences in frustration tolerance, in ego-adaptive and defensive development, in superego maturation, and in the adequacy of object relations and self-representation.

Wide variations in tolerating frustration are to be found not only in comparisons of one individual with others, but also in comparisons of the same person's tolerance level at different times and under varying conditions of stress. Moreover, one person may exhibit low general frustration tolerance (*i.e.*, he reacts maladaptively to almost any frustration) while another may exhibit low specific frustration tolerance (*i.e.*, he reacts maladaptively to some particular kind of precipitating factor but not to others). This multiple variability in frustration tolerance helps account for the great range found in both intensity and variety of precipitating factors in abnormal psychology.

Ego-adaptive and ego-defensive development are directly related to a person's ease of regression under stress, to the completeness of his regression, and to the depth to which his regression goes. In general, the more realistically a person has adapted to his social environment and the richer his psychological resources, the less likely he is to lose his grip on reality when frustration forces him into a withdrawal. The stronger and more mature his ego-defensive organization and the less it is dominated by denial, projection, and introjection, the less likely is regression to bring the sudden eruption of primitive processes. Thus, mildly defective repression and the ready use of projection may result in a neurotic phobia that is not at all disabling, whereas severely defective repression and the ready use of projection may lead to a paranoid psychosis.

Defective superego maturation goes hand in hand with defective ego development, but its effects are sometimes more striking. Thus, susceptibility to severe inferiority feelings, an unfailing indicator of superego pathology, often appears in persons who adapt well to reality in most important respects, even though with greater than average effort. Likewise, susceptibility to psychotic depressions often appears in adults who have managed to handle their lives responsibly and well. It is only when frustration becomes acutely intolerable and such a person grows seriously depressed that one infers how powerful a fixation in primitive superego functioning he has been hiding most of his life.

IV. ABNORMALITIES OF BEHAVIOUR

Abnormalities of behaviour have always been difficult to classify because, no matter how the diagnostic groupings of symptoms are defined, each actual case will exhibit symptoms belonging to more than one diagnostic category. A compulsive person may have a sudden phobia, or a phobic person may show minor compulsive trends. A schizophrenic may be subject to depressions and a depressed person may have brief periods of temporary disorganization. The most common procedure in classification is to determine what seem to be the dominant pathological characteristics, name the disorder accordingly, and bear in mind constantly that such naming is a convenience and not a final judgment.

The current official classifications are oriented primarily to

ward mental hospital diagnosis and statistical recording. Consequently, they stress heavily the illnesses characteristic of a mental hospital population rather than those most commonly seen in office consultation and therapy. Brain disorders and psychoses, for example, make up 50% of hospitalized illnesses, whereas the psychoneuroses make up less than 10%. In what follows, a few of the most typical varieties of abnormal behaviour encountered in the community outside mental hospitals will be described.

A. NEUROTIC REACTIONS

Four of the chief pathological reactions seen in neurosis are discussed fully in the article on neuroses, and hence will not be dealt with here. For anxiety reactions, phobic reactions, conversion reactions, and obsessive-compulsive reactions, see **NEUROSES: Types of Psychoneurotic Disorders**.

A fifth type of common diagnosis is that of psychosomatic disorders, called also organ neuroses or somatization reactions. What all these names refer to is a variety of disorders in the functions of such body structures as internal organs, blood vessels, and glands. The disorders are either the direct product of continued emotional disturbance or at least an intensification of symptoms by emotional disturbance.

Recognition that internal organs, blood vessels, and glands are affected by strong emotion is by no means new, but the systematic study of their emotional disturbances, the field of psychosomatics, is relatively recent. So is the realization that many chronic organic disorders may have primarily an emotional origin and that structural changes may result from prolonged emotional stress. Among the disorders that have been most emphasized are stomach ulcer, colitis, vascular hypertension, aching in postural muscle systems and joints, allergies, asthma, and skin rashes.

To understand psychosomatic disorders it is necessary to bear in mind three things: (1) that emotional expression normally involves widespread changes in internal organs (e.g., diarrhea or loss of appetite during fear), in blood vessels (e.g., flushed face during anger or love), and in glands (e.g., sweating and urinary hypersecretion in anxiety); (2) that intense emotional expression can continue for long periods of time with little relief; and (3) perhaps most important of all, that a person may be unaware most of the time that he is emotionally disturbed. He is most likely to concentrate on his somatic symptoms and to seek help on this basis; he may resent any mentalistic interpretation of them as an insult. Although dramatic and lasting improvement sometimes follows psychotherapy in psychosomatic disorders, the results may not be so gratifying if the disorder is of long standing. It should be added that sometimes a psychosomatic disorder can be the best defense against other symptomatology (e.g., a stomach ulcer may substitute for a serious depression), and it is sometimes in the patient's best interest to avoid intensive psychotherapy.

There is considerable controversy as to whether or not psychosomatic disorders can be clearly differentiated from anxiety reactions and conversion reactions. A distinction between psychosomatic disorders and anxiety reactions is attempted on the grounds that the former focuses on one organ or one system in any given person, while in the latter most or all visceral systems are involved. As for conversion reactions, some diagnosticians stress perception and voluntary motor functions rather than internal organs, blood vessels, and glands. However, the position of psychosomatic disorders in relation to the psychoneuroses must be regarded as unsettled in the 1960s.

B. PSYCHONEUROSES AND PSYCHOSES

Turning to a discussion of the psychoses, the question of their relationship to neuroses (psychoneuroses) arises. In the past this relationship was conceived in different ways. According to one view, psychoses are fundamentally different from psychoneuroses in origin and in dynamics. They are basically manifestations of brain defect or disease, or of disturbances in physiology or biochemistry, whereas psychoneuroses are products of personal stress. According to another view, psychoses are only graver manifestations of the same fundamental mentalistic processes as those un-

derlying psychoneuroses. By the 1960s a growing number of psychologists were interpreting both types of abnormality as arising from the interaction of physiological and experiential elements.

C. PSYCHOTIC REACTIONS

1. Paranoid Reaction.—This illness is characterized by persistent delusions, usually persecutory but sometimes grandiose, without the presence of hallucinations. General behaviour and emotional response are consistent with the patient's ideas, and there is little or no impairment of intelligence aside from the delusions. Paranoia is a rare form of paranoid reaction in which there develops, slowly and progressively, a complex, intricate, and logically elaborated delusional system. The commoner paranoid state is not so highly systematized and elaborate, is sometimes of brief duration, and often ends in symptomatic recovery.

Paranoid states are most likely to arise in tense, insecure persons who are basically mistrustful of others and of themselves and who are ill at ease in interpersonal relationships. The paranoid illness is sometimes precipitated by a person's regressing in the face of serious frustration. Paranoid symptoms may also be seen in such infectious disorders as paresis (see **VENEREAL DISEASES: Syphilis**).

In the common persecutory variety, the patient begins to see signs of aggression and evil intent in the actions of people around him. His vigilance grows in such a way that he becomes increasingly alert to further evidence that he is in personal danger. Regression has reduced the effectiveness of his reality testing to a point where he can accept only evidence that confirms his delusional suspicions. His need for an explanation leads him to believe that the signs of hostility he sees are part of a plot of which he is the focus. The more fixed this belief becomes the more difficult the patient is to treat.

The paranoid reaction illustrates clearly two defense mechanisms, denial and projection. When the patient regresses, his already defective repressive defenses become still more ineffectual, and he experiences a breakthrough of id derivatives, especially aggressive ones. To escape ego disintegration he denies and projects the impulses he can no longer repress, and he misperceives in other people (real ones and imagined ones) the aggressive intentions which are actually his own. His persecutory delusion is thus a reconstruction of his human environment in such a way that what actually threatens to destroy him from within seems to threaten him from without. It goes without saying that this achievement neither gets rid of the threat nor leads toward a happy solution. (See also **PARANOID REACTIONS**.)

2. Schizophrenic Reactions.—Schizophrenia, or dementia praecox, seems to include a number of psychotic disorders which have in common certain basic disturbances in reality relationships, thought processes, and emotional response. Delusions are commonly less well organized and more fantastic than in paranoid reactions, and hallucinations are usually present. Schizophrenic patients show a marked tendency to withdraw from contact with other people, to regress deeply and disorganize.

It is convenient to distinguish four general types of schizophrenia on the basis of symptomatology. (1) If delusions predominate, the condition is called paranoid schizophrenia. The delusions, characteristically vague and fantastic, may be of persecution, grandeur, magical influence, or body change. (2) If, instead, the patient's most prominent symptoms involve motility, the condition is termed catatonic schizophrenia. The catatonic patient postures, gestures, shows great excitement, or grows mute, motionless, and sometimes stuporous. (3) If the patient behaves in a silly, giggling way, with peculiar mannerisms and evidence of hallucination, the disorder is called hebephrenic schizophrenia. (4) If there is an insidious, progressive withdrawal and personality impoverishment, a general deterioration without dramatic symptomatology, the term used is simple schizophrenia. It must be emphasized that patients seldom correspond exclusively to one of these general types. There is much overlapping, and a patient may shift from one type of symptomatology to another.

Controversies over the origin and nature of schizophrenic reactions continued in the 1960s. Aside from evidence of a hered-

itary basis for these disorders, experiments with mescaline demonstrate that florid hallucinations and weird distortions of the body image resembling those reported by schizophrenics can be produced in normal adults. Lysergic acid and other toxic substances also result in the production of schizophreniclike symptomatology (see SCHIZOPHRENIA).

3. Affective Reactions.—This group is characterized primarily by a severe mood disorder, either depressive or elated, with disturbances in thought and general behaviour in keeping with the mood. Psychotic depressions are either agitated, in which case sustained tension, overactivity, despair, and apprehensive delusions predominate, or retarded, in which case the patient is slowed up, his activity is reduced, he is sad and dejected, and he suffers from self-depreciatory and self-condemnatory delusions. Suicidal attempts are common and often successful. Manic excitement is a circumscribed psychotic episode of elation or self-assertive aggression, usually with grandiose delusions.

Although most patients who suffer a depression do not ever develop a frank manic attack, and few with mania ever become frankly depressed, there is a close relationship between the two illnesses. While recovering from a depression, many patients go through a brief period of overoptimism and mild euphoria; and manic patients sometimes have transient episodes of gloom and self-depreciation. A minority of patients actually do pass from a depression into an elation, or vice versa, and some of these go through whole cycles of mania and depression. The current term, manic-depressive psychosis, is derived from *folie maniaco-mélancolique*, introduced in the 17th century.

Statistical studies tend to support the idea of a hereditary predisposition in affective disorders. Some have postulated a large-scale metabolic disturbance to account for the dramatic contrast between a slowed-up, retarded, depressed patient and an excited manic.

Significant environmental precipitating factors can be demonstrated in a great many affective reactions, but not in all. It is believed by some psychoanalytic theorists that a predisposition to affective psychoses lies in abnormal fixations at an immature, dependent level of development. This is thought to leave a person especially vulnerable to deep regression in adulthood, but not to the disorganization characteristic of schizophrenia. The controversy over the origins of affective reactions is far from settled. Its literature is much more sparse than that of schizophrenia.

4. Brain Disorders.—Many diagnosticians include under this head what may also be called toxic and organic psychoses. About 20 different varieties are distinguished. The commonest changes in mental function found in brain disorders are (1) impairment of intellectual abilities, memory, judgment, speech, perception, and orientation; (2) shallowness or instability of emotional response; and (3) alteration in general personality or character.

Brain injury, brain disease, and brain intoxication can result in such changes, either gradually or acutely. So also can general systemic disorders if they interfere with the supply of nourishment and oxygen to the brain or interfere with the removal of waste products. Only one type of brain disorder will be discussed here: that occurring in old age. In old age the brain gradually shrinks in size, certain types of cells disappear and the blood vessels harden. If the blood vessels suffer serious damage, the brain changes may be extensive and may come on suddenly.

Among persons with aging brains will be found all the basic characteristics of brain disorder. The aged person grows forgetful, and he unintentionally distorts what he does recall. He becomes unable to continue at his usual level of work, especially if it involves meeting new situations and making new judgments. He may grow confused about his surroundings, particularly at night and in strange places. He tends to become tearful easily, but he can often be cheered up quickly and even made to laugh through his tears. He may be easily annoyed and he may have temper tantrums. Sometimes striking changes in general character develop. Usually these are only exaggerations of previous personality traits, but occasionally they appear as something new. A kindly, considerate person grows selfish, harsh, and vindictive; a morally strict person becomes involved in antisocial activities; an

honest, reliable person steals, equivocates, or embezzles.

Much remains to be learned about the physiological correlates of abnormal behaviour. Some patients with widespread cellular destruction in the brain show relatively little behavioural deterioration or character change during life. Others with only moderate cellular destruction show considerable behaviour pathology.

In general, old people who live in a peaceful environment, where they experience reasonable satisfaction of their emotional needs, seem to suffer much less deterioration than those whose lives are frustrating, empty, or in turmoil. The patterns of functional change which develop with senility seem usually to correspond to the patient's previous personality, and to the structure of his social environment, as well as to his pattern of senile brain decay. Eventually, however, if the brain grows sufficiently incompetent as an organ, its owner will decline to a vegetative existence no matter what his present situation or his personality structure. (See also DEMENTIA.)

PSYCHOLOGY, APPLIED, describes the use of the findings and methods of scientific psychology in solving practical problems of human behaviour. A more precise definition is impossible because the activities of applied psychology range from laboratory experimentation through field studies of specific utility to direct services to troubled persons. Its practice is not fully controlled by professional or legal methods; there is a zone in which charlatans operate for personal gain. The intelligent layman's major protection against fraudulent practitioners lies in his general knowledge of psychology and in investigating the qualifications of the psychologist whose help he seeks.

This article, which attempts to make reference to all the major areas of applied psychology excluding educational psychology (q.v.), is organized as follows:

I. The Field

A. History

1. Early History
2. World War II Period
3. After World War II

B. Applied Psychology as a Profession

II. Psychology as Applied to Treatment

A. Clinical Psychology

1. History
2. Activities
3. Professional Aspects
4. Training

B. Counseling

1. History and Philosophy
2. Activities
3. Counseling and Psychotherapy
4. Professional Aspects

III. Industrial Psychology

A. Vocational Guidance

1. History and Scope
2. Methods and Functions

B. Personnel Selection, Placement, and Training

1. Selection and Placement
2. Training

C. Hours of Work and Physical Environment

1. Fatigue
2. Hours of Work
3. Scheduled Rest Pauses
4. Illumination
5. Atmospheric Conditions
6. Noise

- D. Work Methods and Machine Design
 - 1. Methods of Work

 - 3. Machine and Instrument Design and Man-Machine Systems
- E. Social and Economic Conditions
 - 1. Social Conditions
 - 2. Economic Conditions
- IV. Other Areas of Applied Psychology
 - A. Engineering Psychology
 - B. Motivational Research
 - C. Forensic Psychology

I. THE FIELD

Psychology deals with the origin, development, and modification of behaviour. The systematic study of psychology includes genetic and physiological bases of behaviour; the social and cultural setting in which behaviour occurs; learning theory and the modification of behaviour via learning; personality theory and the motivational forces producing normal and abnormal behaviour; measurement theory and methods for the quantification of behaviour; experimental and statistical methods for the assessment and prediction of behaviour under defined conditions. The applied psychologist is trained first in these areas of knowledge and in specific techniques; to them is added a period of specialized research or apprenticeship in the area of his particular interest.

A. HISTORY

The same intellectual streams whose confluence produced psychology as an independent subject in the latter part of the 19th century led to the later development of an applied psychology. Philosophy, physiology, evolutionary theory, naturalism, and measurement concepts borrowed from the natural sciences contributed to the new discipline. Self-analysis and introspection, as a basis for speculation about human activity, gave way to controlled observation and study. In Germany, England, and France these ideas took shape in laboratories, technical journals, and books. (See PSYCHOLOGY, HISTORY OF.)

1. Early History.—Francis Galton's publication in 1883 of *Inquiries Into Human Faculty* foreshadowed the measurement of individual differences. In 1896 Lightner Witmer established at the University of Pennsylvania, Philadelphia, a clinic that was a forerunner of clinical psychology. Intelligence testing began with the work of Alfred Binet and Théodore Simon in the Paris schools; the publication of their classic scale for intelligence in 1905 was followed in 1908 by H. H. Goddard's translation of the French mental age scales and in 1916 by the U.S. standardization of the Stanford-Binet scale by Lewis M. Terman and his associates. In France in 1905 J. M. Lahy was studying the abilities required for typewriting and street-car driving. In Britain work with group tests was started in 1911 by the London County Council Education Authority. *On the Witness Stand* (1908) and *Psychology and Industrial Efficiency* (1913) by Hugo Münsterberg extended psychology into two additional areas of application. Sigmund Freud's writings gave major new insights into human motivation (see PSYCHOANALYSIS). William McDougall's ideas about instincts and sentiments aided the understanding of human behaviour. In Britain Cyril Burt, then W. Boyd and J. Drever applied psychology to the problems of delinquency. In 1913–14 E. L. Thorndike published his *Educational Psychology*. At the Carnegie Institute of Technology a division of applied psychology was established as a teaching and research department in 1915 by Walter V. Bingham. The *Journal of Applied Psychology* appeared in 1917 along with the first applied psychology text, by H. L. Hollingsworth and A. T. Poffenberger.

During World War I psychologists in the U.S., Britain, France, Germany, and Italy developed tests for such things as night vision, and for the selection of pilots, drivers, and telegraphers. In the U.S. Army, more than 2,000,000 men were tested and classified for military service by the Army Alpha test battery. In the period 1919 through 1921 four applied psychology organizations independent of universities were established: the Scott Company (U.S.), founded by Walter Dill Scott; the Psychological Corporation (U.S.), founded by J. McKeen Cattell; the National Institute of

Industrial Psychology (Great Britain), established by C. S. Myers; and the Personnel Research Federation (U.S.), directed by Bingham.

Between World Wars I and II the basic findings of general psychology and the special techniques of practitioners came to be applied in courts, clinics, and hospitals, classrooms, libraries, and museums, factories and offices, social service agencies, and government bureaus. Even the great depression of the 1930s was a period of expanding activities; vocational counseling was extended to the unemployed, buying habits of the public were analyzed and opinion polling became an aid to government policy formulation.

2. World War II Period.—Many problems related to the war involved the understanding, prediction, and management of human behaviour. To select and assign persons for military duty, psychologists devised or adapted tests to aid in efficient and rapid classification. Since learning time was short, psychologists worked on problems of efficient and rapid learning at all levels of military training. With manpower in short supply, persons judged to be illiterate or undereducated had to be brought to a minimum level of literacy; psychologists worked with such groups. At the point of induction, those whose personalities would probably break under the strain of military service had to be screened out; psychologists worked with medical specialists in devising more effective screening methods.

Polling methods were developed for evaluating the morale and attitudes of military personnel; psychologists were members of research teams working on studies of stress, as in flight, submarine, espionage, and combat operations, to determine which persons might best be assigned to these functions and what stress conditions would create dangerous decrements in human functioning. As new machines of war were developed, psychologists studied man-machine relations to increase speed of training, increase equipment effectiveness, and simplify and improve the design of military equipment.

As the number of physical and psychological casualties of war increased, rehabilitation and reassignment to limited duty became problems to which psychologists—as clinicians, as rehabilitation specialists, and as co-workers with specialists concerned with restoration of lost bodily function—turned their attention. Leadership, group effectiveness, and survival under stress were major concerns, and psychologists conducted field studies of leadership, morale, and combat operations. In cases of military discipline and delinquency, the methods of clinical psychology, counseling, and rehabilitation of offenders were employed in corrective programs.

In civilian life, psychologists concerned themselves with methods for war bond sales; assisted in developing child-care and day-care centres for families temporarily disrupted by civilian employment or military service; helped with the evacuation of children, and studied the effects of air raids; and concerned themselves with spread of rumour, use of propaganda and psychological warfare, and collecting intelligence data. With the end of the war, civilian readjustment and veterans' benefit programs required great increases in clinical and counseling services, and government training programs for specialists in these fields of applied psychology were established. The political climate of the postwar years required continuation of applied psychological research and services and accounted in part for the rapid growth of many fields of psychology. Both in the United States and in Britain, for example, each of the military services maintained specialist groups of psychologists, and each supported both contract and in-service research programs on a wide range of military problems related to human behaviour.

3. After World War II.—Many of the trends in applied psychology were accentuated by the demands of the space age. Educational psychology is applied to the task of early identification and discovery of talented persons as it has become recognized that trained intelligence is an important national resource. Such activities are linked with the work of counseling psychologists, who seek to help persons clarify and attain educational, vocational, and personal goals. Counseling services sponsored by U.S. government agencies, social service organizations, schools and colleges,

and offered by private practitioners are available. Concern for the optimum utilization of human resources also has increased the importance of industrial psychology in business and industrial organizations. The aviation industry and the various space agencies and organizations have been important factors in the rapid development of the field of engineering psychology; as machines and engineering systems have grown in complexity it has been necessary to study man-machine relationships. In response to society's concern for treatment of the mentally ill and for preventive measures against mental illness, clinical psychology has shown the greatest absolute growth rate within psychology; it also has produced some of applied psychology's major professional problems, involving as it does relations with older medical specialties. The application of automation is being studied by psychologists, and in the developing countries psychologists are being used to help with the problems of rapid industrialization and manpower planning.

B. APPLIED PSYCHOLOGY AS A PROFESSION

Until about 1940 the majority of psychologists held academic appointments, but after World War II there was a great increase in the number of psychologists engaged in work outside institutions of higher education. Support for such activities, including research, came from the military services, government agencies, and business and industry.

In the United States, where this development was most marked, the American Psychological Association was active in developing a code of ethics for practitioners, examining relationships with other professions, and supporting through consultation the licensing or certification of psychologists in many states. In 1947 the American Board of Examiners in Professional Psychology was independently incorporated to grant diplomas representing special competence to experienced psychologists in the clinical, counseling, and industrial fields; by the 1960s the number of diplomates exceeded 1,600, and continued to grow. Great Britain, with an early emphasis on educational and industrial psychology, was a leader in engineering psychology and in applied social psychology in industry. Australia and New Zealand were particularly active in industrial psychology, as were the Scandinavian countries. Counseling received much attention in India and Japan as well as in France, which was particularly important in the historical development of clinical psychology. Industrial and educational applications were characteristic of German psychology. (A. H. Br.)

II. PSYCHOLOGY AS APPLIED TO TREATMENT

A. CLINICAL PSYCHOLOGY

Clinical psychology is concerned with the assessment and alleviation of the problems of persons who are defective or emotionally ill. It can be understood properly in any one of three ways: as a type of personal service performed by psychologists; as a professional subgroup of psychologists having commonly recognized and self-imposed standards of training and practice together with sanctions designed to ensure compliance with those standards; or as a special area of scholarship within the main body of psychological knowledge.

1. History.—Clinical psychology emerged at the beginning of the 20th century with the establishment of individualized treatment programs for disturbed or handicapped children. At first the emphasis was upon sensory handicaps and basic defects in muscular skills. The clinic established by Witmer in 1896 had such an emphasis and, moreover, it dealt with children whose problems arose primarily in school.

The practice of clinical psychology in hospitals and in collaboration with physicians dates also from the turn of the century. A psychological "laboratory" was established by Shepherd Ivory Franz at the McLean Hospital in Waverley, Mass., in 1904 and was continued under Frederic Lyman Wells. In 1909 William Healy, a physician, founded the Juvenile Psychopathic Institute—later the Institute for Juvenile Research—in Chicago. At the beginning Healy, a psychiatrist who also had had psychological training under William James at Harvard, and Grace M. Fernald, a psychologist, constituted the entire professional staff. Clinical psychology as

practised in the tradition established by these two ventures has been characterized both by its mutually supportive collaboration with advanced medical practice and by its attention to the so-called dynamic or motivational factors in the human personality.

Another current in the stream of clinical psychology started with the publication of the first successful intelligence scale by Binet and its subsequent adaptations by Goddard and Terman. Through these events the practice of clinical psychology came to be characterized by the use of relatively objective measures of psychological functions with, nonetheless, continued emphasis on dealing with troubled persons one at a time and taking into account those personal factors still requiring, in large measure, the psychologist's judgment.

At the beginning of World War II there were between 400 and 600 trained clinical psychologists in the United States. In other countries, except for the fact that the numbers are disproportionately smaller, the figure is difficult to estimate, primarily because in other countries the clinical psychologist is more difficult to identify. By 1943 the armed services of the United States were employing 1,500 persons as psychologists, a third of them in assignments that might be called clinical; a large proportion of these persons, however, had had inadequate training. At the end of the war the U.S. Veterans Administration adopted a policy of employing clinical psychologists in all its hospitals and clinics; the U.S. Public Health Service and the various state mental health authorities moved in a similar direction; and child guidance clinics, as well as public and private schools, created new positions. By 1964 clinical psychologists in the United States numbered more than 7,000. In Great Britain most clinical psychologists are employed in the National Health Service; in 1964 there were 356 established posts.

In addition to the types of positions mentioned above, there are also places for clinical psychologists in industry, where some specialize in services to emotionally disturbed employees and others in services for managerial officials who need psychological consultation to help them cope with work stresses and interpersonal problems. Other clinical psychologists serve the courts in assessing psychological factors that bear upon judicial decisions; others serve prisons; some are employed by the armed services; and some teach. Many, in all types of positions, are engaged in research. A small proportion are in private practice.

2. Activities.—Clinical psychologists generally classify their essential activities under three headings: psychodiagnosis, psychotherapy, and research. In psychodiagnosis emphasis is placed on skill in the administration and interpretation of psychological tests particularly those administered to one person at a time. Such tests are described in the article *PSYCHOLOGICAL TESTS AND MEASUREMENTS*. Less formal diagnostic procedures also are employed including the psychodiagnostic interview. In psychotherapy a variety of methods is used (see *PSYCHOTHERAPY*). Research generally is considered to be a further obligation for the clinical psychologist, but it is often crowded out of his schedule; in some cases, where research is undertaken as a primary service to the client, it continues to be, because of the skills employed, a clinical service.

A considerable number of clinical psychologists perform their services in hospitals and clinics. The patterns of collaboration between clinical psychologists and their colleagues in medicine and social work vary greatly among such institutions. The variations are most marked with respect to psychotherapy; some institutions assign most psychotherapeutic duties, particularly work in behaviour therapy, to clinical psychologists, others to psychiatrists only. Institutional collaboration with pediatricians follows a more regular pattern, the clinical psychologist being more likely to be held responsible for services requiring his clinical skills.

3. Professional Aspects.—Clinical psychology gradually is assuming organized responsibility for its own standards of training and practice. This development was considerably delayed because of the conviction, widespread among psychologists, that the sanctions and restraints of a profession are antithetical to liberal scholarship and that they would impede the advancement of psychology as a science. Because of the threat of restrictions im-

posed from organized psychiatry, however, clinical psychologists were reluctantly joined by their colleagues in an effort to establish standards of training and practice and to provide legal refuge for the continuing development of psychology as a whole. Thus U.S. psychology, and especially clinical psychology, sought to achieve a body that was at once both science and profession.

In Britain the development of clinical psychology is less formal, and this is enabling the psychologist to extend his work to many departments in general hospitals as well as in mental hospitals, especially in the field of rehabilitation.

4. Training.—The pattern of training for clinical psychologists in the United States was established by a committee headed by David Shakow during the 1930s. A broad training in psychology as a science and in related disciplines, as well as demonstration of research competence, was recommended for the doctor of philosophy degree, to which were to be added practicum courses and a fourth year of graduate training to allow time for internship in an interdisciplinary setting.

The American Psychological Association, through its Education and Training Board, annually identifies universities and internship agencies that meet its standards. The American Board of Examiners in Professional Psychology certifies selected advanced specialists in psychological practice, including clinical psychologists, after examination. As a general guide to the practice of professional psychology the association developed a code of ethical standards, which was accepted by its membership and is used as a basis for disciplinary action against those who fail to conform.

(G. A. KE.)

In Great Britain the training of clinical psychologists takes place either in departments of psychology in universities, where diplomas are awarded, usually after two years post-graduate training, or as in-service training for three years in a mental hospital under the direction of a senior psychologist. Regional in-service training schemes have been developed to give trainees experience with different types of patients, problems, and treatments.

B. COUNSELING

In psychological counseling a psychologist participates in interviews with a client for the purpose of increasing the client's level of personal integration. This definition emphasizes (1) that treatment proceeds through communication; (2) that the motives and personality structure of the client are the focus of interest; and (3) that the help offered is nonspecific. This latter means essentially that total personality organization is considered. Such issues as marital, sexual, job, and educational problems and symptoms are not the main concern of the counselor, although they may be resolved as part of the counseling process. Influence rather than guidance is the aim; adjustment of the client, in the sense of fitting in or of conforming to the environment, is not a goal of the counselor.

1. History and Philosophy.—Before 1940 the goal of the counselor would have been to help his client to find some educational or occupational environment conceived to be optimal. The main function of the counselor was to assess personal and environmental possibilities so that the client might make reasonably realistic educational and vocational decisions.

Counseling psychology has its roots in two distinct traditions, both established at the turn of the century. The first is that of mental testing, the second that of vocational guidance (see below), as influenced by Frank Parsons and others, with emphasis on matching person and environment. Originally interests, aptitudes, and abilities were given great weight in the counselor assessment of the client. Later, after intelligence tests and personality inventories had been found useful in World War I, the assessment came increasingly to be based upon the results of mental tests and psychometric methods. Since psychometric methods required considerable sophistication in the psychology of individual differences and statistics, the professionalization of counseling began under the influence of the mental test movement.

During the period between World Wars I and II great emphasis was placed upon quantitative assessment of the person and also of his educational and occupational environment. If the client was

too maladjusted to discuss and make decisions rationally, he was referred to a psychotherapist; the counselor's client was supposed to have vocational and educational problems only through misinformation or lack of information.

World War II brought to the attention of counselors the notions of personality structure and dynamics. In 1942 Carl R. Rogers published *Counseling and Psychotherapy*, in which he stressed the counseling process rather than diagnosis and assessment; he brought together the traditions of counseling, guidance, and psychotherapy.

2. Activities.—While Rogers' recommendations with regard to treatment deeply influenced professional practice in many ways, his emphasis upon personality development and psychological growth processes was even more influential. The great difference in emphasis can be seen by comparing a textbook such as E. G. Williamson and J. G. Darley's *Student Personnel Work* (1937) with E. S. Bordin's *Psychological Counseling* (1955) or with J. Hadley's *Clinical and Counseling Psychology* (1958). In the first text "psychotherapy" does not appear in the index; in the latter two counseling and psychotherapy are used as virtual synonyms, the distinction being one of degree only. The tendency to identify counseling with psychotherapy, however, is not so significant as the tendency to think of counseling and psychotherapeutic processes in terms of the general psychology of behaviour. Whereas formerly counseling and psychotherapy were discussed in, for example, the specialized terms of individual differences, mental test theory, and psychoanalysis, there has come to be a distinct tendency to relate them to the general psychology of learning, behaviour, and perception.

3. Counseling and Psychotherapy.—In focusing on the modification of personality, the psychological counselor approaches the field of the psychotherapist. Are there useful differentiations to be made between counseling and psychotherapy? With regard to the psychological processes involved the answer is probably no; they are identical. Counseling and psychotherapy are indistinguishable with respect to their primary goal: modification of personal organization in the direction of increased personality integration. Psychological counselors usually assume more of a distributive function. Assessment of aptitudes, abilities, and interests in relation to educational and vocational goals occurs much more often in the counseling than in the psychotherapeutic situation.

Besides the difference in approach, psychotherapists and counselors serve a somewhat different clientele, although there is a very large overlap. Psychiatrists and psychotherapists, by custom and often by law, tend to serve persons whose lack of personal integration is severe enough to be incapacitating or to render them dangerous to themselves or others. Counseling psychologists seldom work with persons so severely ill; when they do so, they conventionally place themselves under medical supervision. In sum, the distinction between counseling and psychotherapy is essentially one of degree, not of kind.

4. Professional Aspects.—In the United States the trends discussed have resulted in an increase in professionalization, and with this has come an increased demand that psychological counselors have the Ph.D. degree and increased emphasis within graduate training programs on the psychotherapeutic aspects of the counseling process and upon mastery of projective psychology and projective tests. In other countries, counseling is yet to be regarded as a distinct profession. However, it is becoming clear that the trends on the American side of the Atlantic are having some effect on the European side. In Japan a deep interest in psychoanalysis, Rogerian psychotherapy, and counseling has developed. The Japanese seem not to make the intellectually arbitrary distinctions forced upon Americans by their history; consequently interaction and mutual influence among counselors, clinical psychologists, and psychotherapists is possible and evident to a degree not realized in the United States and Europe. See also PSYCHOTHERAPY.

(J. M. BU.)

III. INDUSTRIAL PSYCHOLOGY

Industrial psychology is concerned with the utilization and conservation of industry's human resources. This is accomplished by

the study of people at work and by the development and application of principles designed (1) to increase production; (2) to promote individual satisfaction and adjustment; and (3) to establish a basis for harmonious relations between management and workers.

The application of psychology to occupational problems in the defense services, in prisons, and of school children has encouraged in Great Britain the use of the wider term occupational psychology. The British approach regards occupational psychology as a unity, although it is convenient to subdivide the subject, and this has been shown to be useful in ensuring that mistakes are not made in detecting the causes of manpower difficulties. The distinction is also made in Great Britain between occupational psychology as a science and as a technology. As a science, occupational psychology attempts to provide a precise and comprehensive description and explanation of human behaviour, based where possible on theories; as a technology it is concerned with the effective use of manpower and individual satisfaction with work.

Emphasis on human welfare is to be found in the first detailed program of industrial psychology as formulated in 1913 by Münsterberg, then serving as director of the Psychological Laboratory at Harvard University. In Great Britain the Health of Munition Workers Committee, organized in 1915, and later the National Institute of Industrial Psychology also based research and practice on the view that it is necessary to give the worker greater psychophysical ease at work, as well as to raise output.

A. VOCATIONAL GUIDANCE

Vocational guidance is based upon theories and methods derived from the social sciences, mainly psychology, economics, and sociology. It can assist the person (1) to obtain accurate information about his aptitudes, inclinations, and opportunities; (2) to learn about the world of work, kinds of jobs available, training required, and duties, responsibilities, and rewards of jobs; (3) to integrate this information about himself and about available alternatives so that he can arrive at a realistic and reasonable vocational decision; (4) to make sensible educational and vocational plans that eventually will lead to his vocational objective; (5) to acquire the skills and attitudes requisite for success in his chosen occupation; (6) to obtain a position that provides adequate opportunities for the expression and use of the skills he has acquired; and (7) to develop further skills that will lead to advancement and promotion once he has started his career.

1. History and Scope.—Systematic vocational guidance in the United States had its origins in Boston about 1909, in Parsons' book *Choosing a Vocation*. It began under the sponsorship of community agencies, and such organizations have maintained their interest in it. The schools, however, soon began to express interest, and gradually vocational guidance became largely a school function. Research into the effectiveness of vocational guidance was financed by the British government during the 1930s. Most vocational guidance in the United States is provided by school and college counselors trained in adolescent and developmental psychology, psychological testing and measurement, occupational information, and guidance and counseling methods. In addition, vocational counselors in many state employment offices use a comprehensive system of vocational aptitude tests, the General Aptitude Test Battery developed by the United States Employment Service. The U.S. Veterans Administration expanded its vocational rehabilitation program started for disabled veterans of World War I and, in its advisement and guidance program, provided vocational guidance to millions of World War II and Korean War veterans through counseling centres located throughout the country. Most states, in conjunction with the U.S. Office of Vocational Rehabilitation, provide vocational guidance for physically disabled persons.

In Great Britain vocational guidance is provided for the disabled by the Government Industrial Rehabilitation Service. It is obtainable from private organizations such as the National Institute of Industrial Psychology. The government-administered Youth Employment Service provides career advice for those who leave school. In Australia and Canada schools have assumed

major responsibility for vocational guidance. Vocational guidance in France was officially made a responsibility of the Ministry of Education in 1922, and since 1928 the national counseling service has been known as the Institut National d'Étude du Travail et d'Orientation Professionnelle; in 1963, about 800 counselors were employed in more than 200 guidance centres in France. The first Belgian vocational guidance centre was established in 1912, and in 1937 a national system of vocational guidance was established under the jurisdiction of the minister of education; in the early 1950s between 50,000 and 60,000 persons were provided with vocational guidance yearly in more than 80 local counseling centres. The first vocational guidance bureau in Japan was opened in 1920, and in that country the program has been sponsored by the Ministry of Education, Ministry of Welfare, Ministry of Labour, and the Japanese Vocational Guidance Association.

2. Methods and Functions.—The instruments used in vocational guidance include biographical questionnaires, tests of intelligence, aptitudes and attainment, vocational interest, and personality inventories. Psychological tests provide information that is sometimes useful in predicting success and satisfaction in various occupations. (See also PSYCHOLOGICAL TESTS AND MEASUREMENTS.) The results of these psychological tests are supplemented in interviews by additional information about the person's previous experience and achievement.

Because psychological tests are of limited validity, their use in vocational guidance requires skill and training. In most U.S. states vocational counselors employed in schools must have completed a minimum of a year's work in a graduate school of a university, specializing in guidance, counseling, and psychological measurement.

As important in vocational guidance as test information is occupational information, obtained from such sources as government departments, colleges, universities, professional associations, and commercial firms. Gertrude Forrester's *Occupational Literature*, an annotated bibliography published in 1954, listed approximately 3,200 selected references to occupational literature.

In vocational guidance, relevant occupational information is provided in individual interviews and group meetings. Courses in occupations are taught at the secondary school level, and frequently units in other courses, particularly in the social studies, are devoted to the study of occupations.

Placement, the process of helping persons obtain positions, is another important function of vocational guidance. Persons are taught how to locate positions, write letters of application, behave during employment interviews, and evaluate job alternatives. In a few organizations, counselors and personnel workers are available to assist employed persons in meeting problems encountered on the job. Personnel workers also discuss with employees on-the-job training programs leading to advancement and promotion, relationships with other employees and supervisors, and other matters affecting the worker's vocational adjustment. Thus, vocational guidance is a continuous process. (R. F. BE.)

B. PERSONNEL SELECTION, PLACEMENT, AND TRAINING

1. Selection and Placement.—Application of scientific procedures for matching jobs and workers involves (1) an analysis of the demands of each job in terms of duties, skills, and critical requirements such as causes of difficulty and distaste for the work; and (2) the development of techniques for measuring the aptitudes and inclinations of applicants for employment or transfer to meet these requirements. In the main, such measuring devices take the form of objective psychological tests that are known to have some measure of validity in predicting behaviour on the job. In Great Britain the interview is still the most frequent procedure for assessment.

Many industries have reported striking results from the use of psychological tests, as have the military services. During World War II failures in the U.S. Air Force pilot training program were reduced from 65% to approximately 35% following the introduction of tests for the classification of candidates for pilot training. Another significant trend is the application of psychological techniques for appraisal and development of supervisory and

executive personnel. Not only psychological tests but also rating scales, patterned interviews, and biographical inventories show promise in this area. In fact, such traditional methods, refined and validated, have proved to be more effective in selection for some types of jobs, such as insurance salesmen, than have the tests.

2. Training.—The person who is qualified for a position may become inefficient and even maladjusted without proper training. Principles derived from research on the learning process (see **LEARNING**) are applied to improve quantity and quality of output; to reduce training time; to enhance ease and safety at work. Such research has focused attention on the need for supplementing repetition or routine practice by positive reinforcement. In industry this can be provided most easily and cheaply by giving the trainee immediate and frequent knowledge of results. As an example, in one case a revised program for training radio code operators, in which the correct symbol was given immediately after the trainee had written down each signal as he understood it, reduced by about 25% the time taken by trainees to reach a speed of five groups per minute. The effectiveness of training also can be improved by telling the worker why a job is done in a particular way, as well as how to do it. The psychologist also devises reporting procedures and trains managers and supervisors in their use, so that any training scheme can be followed up systematically to ensure that it is effective. Principles mentioned above and others have been introduced into programs for teaching supervisors to give better instruction on the job. Notable among these is one known as Job Instruction Training (JIT), developed by the U.S. War Manpower Commission, which has been advantageously used in Britain in the Training Within Industry Scheme, and throughout the world.

A highly crucial problem in industry is that of reducing the frequency and severity of accidents. Although some progress has been made, it generally has been found that little benefit has come from tests for measuring accident proneness. On the other hand, training programs in which supervisors make sure that each worker uses only correct methods of work can contribute much to the reduction of accidents (see **INDUSTRIAL ACCIDENTS**).

The application of the techniques of programmed instruction and teaching machines (see **PROGRAMMED LEARNING**) has brought about a major advance in some areas of industrial training. These techniques emphasize the need to state training objectives in detail, to organize learning material into small, meaningful blocks, to present the material so that the trainee obtains immediate knowledge of his performance, and to allow him to learn at his own pace. These programs have encouraged a systematic and empirical approach to industrial training.

C. HOURS OF WORK AND PHYSICAL ENVIRONMENT

1. Fatigue.—One of the significant costs of work is fatigue, which is discussed at length in the separate article **FATIGUE**. The term fatigue has been used to characterize three interrelated phenomena: (1) a decreased capacity for work, known as work decrement; (2) modifications of the physiological state; and (3) tiredness and related feelings.

2. Hours of Work.—During the 19th century a work schedule including a minimum of ten hours per day and six days per week was predominant in industrialized countries. Opposition to reducing hours of work has been overcome by the discovery that production is not adversely affected, indeed is frequently increased, by shortening the working day and the length of the working week. Output does not necessarily fall off with a shortening of the work week because of a tendency for the human being to adapt his rate of work to the length of time available, and to the amount of work to be done.

3. Scheduled Rest Pauses.—It is advantageous to break up a spell of work by scheduled rest pauses. Rest pauses are desirable in that they may heighten motivation and combat boredom as well as reduce fatigue. Furthermore, they may involve no actual loss of time, since workers tend to take equivalent time off, sometimes surreptitiously, and unauthorized "breathers" do not provide the equivalent of scheduled rest pauses in the way of relaxation

and release from tension. Support for well-controlled coffee breaks, tea breaks, or "elevenses" is found in studies showing that the intake of food during a rest pause contributes to its beneficial effect.

4. Illumination.—Unsuitable lighting accelerates the onset of fatigue, chiefly by increasing muscular fatigue in seeing. A major requirement of good lighting is adequate brightness, associated with intensity of illumination. Low intensity continues to present a problem in many factories and offices, where the level of illumination is lower than 5 foot-candles, as contrasted with the 1,000 to 1,500 foot-candles characteristic of the outdoors even on a cloudy day (see **PHOTOMETRY**). Difficulties in measuring the psychophysiological cost of work under varying levels of illumination and other factors have led to disagreements as to applicable minimum standards for different jobs.

Proper diffusion and distribution of illumination, designed to eliminate glare and undesirable shadow effects, are also necessary to see clearly and easily. Brightness contrast (*i.e.*, the ratio between the brightness of the object and that of the background) must be considered in determining the proper type of illumination. Colour may play a part; it has been shown that it is easier to see when contrasting colours are used on machine tools and that this serves to emphasize danger points on the machine as well as to increase efficiency. (See also **LIGHTING**.)

5. Atmospheric Conditions.—According to a study conducted by the American Society of Heating and Ventilating Engineers, 50% of people engaged in light work in the United States find air temperatures of 63° to 71° F (17.2° to 21.7° C) comfortable in winter, and temperatures of 66° to 75° F (18.9° to 23.9° C) suitable in summer. The same percentage select 30% to 70% as the desirable level of relative humidity. However, people vary widely in their reactions to these atmospheric conditions and also to the rate of air movement, which is another important factor in maintaining efficiency and comfort at work. Much depends also upon the nature of the task.

An index known as Effective Temperature (ET) shows the combined effect of air temperature and humidity on the human experience of warmth or cold for a specified rate of air movement. In general, studies indicate that performance is impaired to a serious degree with effective temperatures in the middle 90s F (middle 30s C) or above, and that incentives do not offset the effects of high temperatures. At temperatures below 50° F (10° C) the precision of hand and finger movements is reduced. There are no materially adverse effects on so-called mental activities even at temperatures below 0° F (−17.8° C), although impairment occurs in the performance of manual tasks. Furthermore, both physical and mental processes suffer and feelings of fatigue are increased under conditions of anoxia, or oxygen deficiency, such as occur moderately at an altitude of 10,000 ft. or less and critically at about 20,000 ft. and above (see **HYPOXIA**).

Careful selection of personnel, provision of protective clothing and oxygen equipment, adjustment of the work period, and so on, can ameliorate the effects of atmospheric conditions characteristic of extreme climates and also of work around blast furnaces, in mines and submarines, in flying, etc. However, atmospheric conditions create negligible human problems in modern, well-ventilated, properly heated, air-conditioned plants. (See also **HEATING AND VENTILATION**.)

6. Noise.—Adaptation takes place in the case of regular exposure to expected and continuous noises of high intensity in the work situation, especially in the presence of high incentives. Prolonged exposure, however, to high noise levels and certain types of noises—as, for example, those experienced by boilermakers and airplane pilots—contributes to hearing loss. On the question of direct fatigue effects there is considerable disagreement among research workers. It is probable that excessive noise acts on the human organism as excessive friction acts on the machine; that it wastes energy (see **NOISE AND ITS CONTROL**).

D. WORK METHODS AND MACHINE DESIGN

1. Methods of Work.—Waste in the use of human resources in industry can be curtailed by the elimination of awkward and

unnecessary movements in doing the job. A comprehensive program for doing this, including time and motion study procedures, was developed at the beginning of the 20th century (*see INDUSTRIAL ENGINEERING*). This and a variety of subsequent programs undertake basically to eliminate unnecessary movements and to combine selected motions into a standard method frequently designated as the one best way of work. The concept of the one best way of work has been a matter of concern to psychologists. Involved, in part, is a question as to whether any single rigid pattern of work is uniformly applicable to all workers, since they differ in psychophysical make-up.

Modern programs designed to improve work methods, generally known as methods engineering or work simplification, reflect these newer outlooks. There is an increasing tendency to make use of general rules of motion economy—dealing with such factors as symmetry, continuity, smoothness, and rhythm of movement—as a substitute for rigid patterning of so-called basic motions. Furthermore, many supervisors and also workers are being taught how to apply these rules. The psychologist's concern is to ensure due regard to the characteristics of workers when developing new work methods.

2. Alleviation of Boredom.—Highly specialized, repetitive work, widespread in modern industry, leads to a feeling of boredom; as indicated by both U.S. and British studies, considerable boredom is experienced by approximately 25% of factory workers. Boredom produces a change in the shape of the daily production curve which, contrary to the situation when fatigue is experienced, tends to fall in the middle and to rise at the end of the work period. Furthermore, employees who experience boredom frequently exhibit low morale.

Efforts to develop tests of susceptibility to boredom and assign to repetitive work only those who are not highly prone to it have not been successful. As a result, attention has been turned increasingly toward modifying the work environment. Research has shown that appropriately spaced rest pauses, freedom to engage in conversation, music, and the social environment of the plant, especially as reflected in the formation of closely knit small work groups, tend to decrease boredom.

A high degree of specialization in work has been favoured in the belief that this tends to increase over-all production. However, it has been shown that redesigning jobs so that the worker can perform a variety of tasks reduces boredom and improves general attitudes without adversely affecting production. Thus job rotation and also job enlargement are being used increasingly. These problems are attracting more interest from psychologists as the use of automation increases (*see AUTOMATION*).

3. Machine and Instrument Design and Man-Machine Systems.—With the growth of mechanization in industry, it has become increasingly necessary to view man and his machine as an integrated functional unit. There is continuing need to approach the design of machines with full consideration of basic patterns of human perception, communication, and motor response, and also of built-in limitations in the speed, accuracy, and coordination of these and other human functions. Failure to consider the human element in the design of machines has led to the construction of mechanical monstrosities, such as a mine hoist that requires the operator to stand spread-eagled with his weight resting on one foot to read a dial tilted 30° upward and sideward. Many machines and tools tax the capabilities and energy of human operators.

Since the 1940s there has been growing acceptance of the principle that machines should be made for men rather than men forcibly adapted to machines. This view finds expression in specialized research and practice most frequently described as engineering psychology (*see Engineering Psychology*, below).

Visual Indicators.—The widespread use of such instruments as pressure gauges, tachometers, and voltage meters has led to extensive studies of visual indicators. An example of poor design is found in a control panel 17½ ft. in width where all major gauges were 2 to 3 ft. above eye level. Operator complaints of eyestrain and fatigue led to the redesign of the control panel to a width of 6 ft. with better positioning of instruments for seeing.

Poorly designed instruments can cause accidents as well as

produce unnecessary fatigue. Thus a survey of 270 pilot errors showed that 13% of aircraft accidents investigated resulted from a misreading of the altimeter by 1,000 ft. There is evidence that the substitution of a numerical counter for the conventional type of altimeter reduces the percentage of errors in reading from 11.7 to 0.4 in the case of experienced pilots. Studies of many kinds of visual indicators have led to the formulation of principles designed to improve both the ease and accuracy of instrument readings, covering such characteristics as intervals between scale markings, size and style of figures, shapes of pointers, and conditions of illumination.

Controls.—The placement, shape, and direction of movement of controls represent important factors in design. Wide separation of controls leads to reduction of output and to increase of effort in the operation of machines; by contrast, major controls placed too close together may produce accidents. The latter has been demonstrated in aircraft accidents where the closeness of the flap control to that used for the landing gear led to accidental operation of the wrong control.

Coding.—Strain can be reduced and safety increased by coding or associating differently shaped controls with distinctive operating functions. Basic principles include the rule that for adjusting a lever or control knob the movement should be in the same direction as the perceived adjustment. Thus toggle switches should move upward for on, go, or increase, and downward for off, stop, and decrease.

E. SOCIAL AND ECONOMIC CONDITIONS

In many instances, hours of work and physical conditions play a less important role than the psychological, social, and economic conditions prevailing in a factory or office in determining the behaviour of the working force. These conditions are largely determined by the personnel practices of the company, and its supervisors and executives.

1. Social Conditions.—Social Relationships.—Studies conducted in the Hawthorne, Ill., plant of the Western Electric Company between 1927 and 1932 attracted attention to the significance of social aspects of the work situation. These studies included extensive observations of the effects of changes in number and distribution of hours of work, illumination, rest pauses, wage-payment plans, etc. Such changes were accompanied by increased production, but the upward trend did not disappear when the favourable physical conditions were eliminated. It was concluded that the production increase was the result of a change in the social situation. The conditions of the experiment apparently created a relationship between the employees and their supervisors which did not exist ordinarily. Employee motivation seemed to change in response to increased attention from management. The studies were reported by F. J. Roethlisberger and W. J. Dickson.

Subsequent research by different investigators in many plants has clearly confirmed the view that the way the person acts, the way he feels about his job, the level of his morale—in the sense of willingness to strive for the goals of the company—are very much affected by the sentiments and attitudes of his co-workers. Of particular significance is the influence of the small work group or team to which he is assigned by management, and of the small informal organization which develops spontaneously as a function of the work situation. The influence of the social situation is intensified because the employee is simultaneously a member of many groups, and because some of these (e.g., the company and the union) may be competing for his interest and his loyalty (*see PSYCHOLOGY, SOCIAL*).

Work Groups.—A study conducted in two British automobile factories showed that higher production and greater satisfaction occur in smaller than in larger work teams. Observation of four gangs engaged in repairing railroad passenger cars in Great Britain showed that, under a group wage incentive, productivity increased at a higher rate in gangs of small size and with a particular pattern of stability than in larger work gangs. These and other studies also yielded evidence of higher levels of satisfaction and morale in smaller work groups.

The explanation of such findings is to be found in the social

structure of the groups. Smaller working groups tend to be more cohesive than are larger groups. Under appropriate conditions, especially in the presence of a high quality of leadership, such cohesiveness leads to higher work standards, to acceptance of technological change, and to better achievement of other goals important to management.

A conscious effort to combine in a work team members who like and are friendly toward each other is conducive to the development of such positive attitudes and behaviour. The advantages of using such cohesive work groups are illustrated in an experiment conducted in the construction industry; total production costs were reduced by 5% when carpenters and bricklayers were permitted to select their own workmates instead of being required to work with arbitrarily assigned teammates.

Democratic Leadership.—A number of studies covering many occupations and many countries—ranging from telephone operators in the state of Michigan to textile workers in India—have demonstrated that an atmosphere of democratic leadership, which provides opportunities for employee participation in setting goals and in other aspects of decision making, results in higher production, greater job satisfaction, and improved morale. Evidence of such returns was first demonstrated clearly in a study conducted in a garment-manufacturing plant, where there was considerable resistance by production workers to necessary changes in jobs and work methods. Providing opportunities for the workers to participate in planning the details of the change and in setting production goals led to higher output, decreased turnover, and a more harmonious relationship between workers and supervisors. Such benefits appear not only when small changes are involved but (as was shown in later developments in a garment-manufacturing plant and in the Indian studies) also where a widespread program of modernization or reorganization is required.

In Britain many joint consultation schemes have been established to provide opportunities for fuller expression of opinions and needs among all grades of the workers.

Experience of companies introducing electronic office equipment and other forms of automation shows further that industry can profit from permitting workers to participate in decision making, without any abdication of the responsibility of management for the operation and growth of the business.

Supervision.—Many studies, including that cited above, have demonstrated that the quality of supervision exercises a tremendous influence upon employee motivation and morale. Studies of work groups, including insurance office workers, labourers in railroad gangs, linemen, etc., conducted by the Survey Research Centre of the University of Michigan, showed that employees who perceive their supervisors as "employee centred" have better production records than do groups working under "production centred" supervisors. There is evidence that absence rate is inversely related to quality of supervision.

Other studies show that the quality of supervision is good when workers feel free to discuss their problems with their supervisor; know what he thinks of their work; feel that the supervisor supports them when they have a complaint; when the supervisor uses general rather than close supervision; when the supervisor frequently conducts group meetings where work matters are discussed.

Recognition of the central role of good supervision has led to supervisor selection programs and extended training programs for supervisors.

Communication.—Small groups become cohesive, in part, because in them information can be passed along quickly. Employees look to supervisors for opportunities to discuss their interests. Adverse attitudes toward company plans change for the better when facts concerning them are properly communicated.

The need for adequate communication exists at all levels. Supervisory personnel often complain of the failure of higher management to keep them informed about matters that are of interest to them and their employees. Formal channels of communication following the lines of the organization chart may not be sufficient for full dissemination of information.

Management Procedures.—Basic principles of good supervision require that supervisors, at all levels perceive themselves and act

as members of the management team. Along with keeping the supervisor informed, it is necessary to define the scope of his responsibility and to delegate to him the authority to use it. One study showed that 79% of foremen with high morale and only 37% of foremen with low morale had a clear understanding of their duties. Similarly, 79% of the former and only 30% of the latter claimed that they had adequate authority to deal with employee and other problems. In addition, the supervisor is at a disadvantage on the job unless his status is made clear by the wage scale and by such physical symbols as desk and office space; and unless he is permitted to play a role appropriate to his rank in policy administration and policy making. Studies of such social factors overlap with those of industrial sociologists. (See also INDUSTRIAL RELATIONS.)

2. Economic Conditions.—This emphasis on the social situation should not draw attention from other and even more fundamental motives, associated with basic drives for food, shelter, job security, and self-expression. Research has thrown considerable light on the sources of motivation (*q.v.*)—on the variety and strength of needs that should be gratified in the work situation.

There is evidence that executives and union leaders err in their judgments of workers' needs and the potency of financial incentives. In one survey 75% of executives and of labour leaders and less than 30% of employees included payment among five factors rated as most important to workers. In a later study workers listed "full appreciation of work done" as first and "good wages" as fifth on a list of morale factors. By contrast, supervisors predicted that "good wages" would turn out to be the most important item looked for on the job by the workers, and that "full appreciation of work done" would rate in eighth place.

This does not mean that the pay envelope is unimportant; a low wage scale is a significant source of dissatisfaction and lack of cooperation. Nevertheless, voluntary restriction of output in plants using wage-incentive systems and strikes in plants with high wage scales show that such factors have limited power as incentives. As wages rise above subsistence level, other needs become more influential. Workers seek such returns as the opportunity of doing something worthwhile; the feeling of being recognized as an individual; a sense of belonging; a chance to get ahead; approval of work done; a safe future; guidance in establishing goals and learning how to achieve them; and the opportunity of contributing from their knowledge in dealing with their own problems.

Although the introduction of a new payment system can have an immediate favourable effect on production, in the long term such efforts can only succeed if sufficient prior attention is given to psychological and social conditions at the place of work.

(M. S. VI.)

IV. OTHER AREAS OF APPLIED PSYCHOLOGY

A. ENGINEERING PSYCHOLOGY

Engineering psychology—also called human factors engineering or ergonomics—seeks to ensure that the tools and machines man uses, and the work he performs, are in accordance with his characteristics. Past efforts to achieve them rested chiefly on the ingenuity of inventors and on practical experience rather than on scientific knowledge of human characteristics. The accelerated pace of technology, the increasing complexity of machines, and the trend toward automation have led to increasing emphasis on efficient man-machine systems. This emphasis resulted in the rapid growth of engineering psychology. This growth can be exemplified in Europe by the Ergonomics Research Society that embraces psychologists, physiologists, anatomists, engineers, and other members of industry.

Work in engineering psychology greatly accelerated during World War II, particularly in aviation. Questions concerning design of aircraft instruments for ease of interpretation, design of flight controls for accurate manipulation, and the matching of man's response characteristics to the dynamic characteristics of aircraft were among the critical problems in military aviation. Similar problems arose with other types of military equipment. Some of these problems were solved with data already available

from experimental psychology; existing experimental methods were used to solve others. Much basic work has had to be done on the dimensions of the human body and on perceptual functions.

One of the oldest problems is the design of signs and symbols—e.g., alphabetic symbols, the signs used on highways, the codes used in telegraphy, and the symbols used in printing for the blind—to increase speed and accuracy in transmitting information. As new display media, such as radar and television, were developed, new problems of visibility, legibility, and ease of interpretation arose; research on display problems continues to be important.

Another class of problems of historical importance involves the design of tools and various types of controls so that they are adapted to human strength, dexterity, speed, and accuracy of movement. The scope of engineering psychology has broadened to include such questions as "How far is it advisable to go in eliminating people and making manufacturing processes completely automatic?" Answers to such questions obviously should be based on analysis of the relative capabilities of complex machines, such as electronic computers, and of human beings in performing comparable tasks.

Engineering psychology applications thus depend heavily on knowledge of human performance characteristics and on knowledge of individual differences, learning, and motivation, as such variables affect performance in man-machine systems.

(P. M. FL.)

B. MOTIVATIONAL RESEARCH

Motivational (motivation) research is concerned with the motivations of human beings as reflected in mass behaviour relating to sales, advertising, and merchandising. Motivational research resembles—and some of the basic fact-gathering methods it uses are similar to those of—public-opinion polling (see PUBLIC OPINION). Public-opinion polls, however, are usually based on predetermined statistical samples of people. Motivational research does not normally use such statistical techniques applied to responses to direct questions. Rather it acts on the assumption that many human motives are unconscious or not readily admitted because they are not always socially acceptable.

The methods employed to uncover underlying motives are borrowed from psychiatry, psychoanalysis, and depth psychology (see PSYCHIATRY; PSYCHOANALYSIS). They include such devices as the depth (nondirective or open-end) interview, projective tests, laboratory experiments, and psychodrama. The depth interview is one in which the subject rarely is asked a direct question; for example, the researcher will not ask him why he bought a particular make of car, but will attempt to infer this from his answers to indirect questions. In using projective tests, it is hoped that inkblots or pictures illustrating specific situations will prompt people to reveal their true motivations (see PSYCHOLOGICAL TESTS AND MEASUREMENTS: *Projective Methods*). Laboratory experiments seek to measure responses to specific people and objects—including products, services, and mass media. In psychodrama, people are asked to act out a purchase, interpersonal relations, or emotional problems; in doing so, they may report insights into their own behaviour, and the researcher may feel he gains understanding of their motivations.

Motivational research, since it attempts to change such activities as voting, buying, and attitudes toward national and international issues, raises a question regarding the ethics of using such methods to influence people, often against their will. Some motivational researchers answer that people always have tried to influence each other and that the real issue is one of determination of the morality of the goals.

(E. D.)

C. FORENSIC PSYCHOLOGY

Part of the scientific research on human behaviour carried out by psychologists and other social scientists is pertinent to a wide range of legal problems. Psychologists have also studied detection of guilt and deception, distortions of perception and memory in relation to testimony, the behaviour of juries, problems related to the determination of competence and sanity, personality and motivational factors related to crime, factors influencing success and

failure on parole, the sociopsychological organization of prisons, the psychology of drug addiction, and the like. (See INVESTIGATION, CRIMINAL: *Methods of Investigation: Detection of Deception*.)

In addition, a number have served as clinical psychologists or guidance counselors affiliated with juvenile and criminal courts, prisons and other legal agencies. Further, psychologists sometimes serve as expert witnesses in cases involving determination of mental deficiency, legal insanity, or other problems in which technical psychological knowledge may be of use.

European developments in forensic psychology have drawn heavily on the techniques and findings of experimental psychologists.

(G. A. R.)

PSYCHOLOGY, COMPARATIVE, the study of similarities and differences in behavioural organization among living beings, from viruses to plants to man. A view of the subject held earlier by W. Wundt and others included human comparisons now generally studied as genetic or child psychology, abnormal psychology, and ethnology or folk psychology. This article is concerned with the psychological nature of man in comparison with other animals.

As animal psychology, comparative psychology centres on discerning qualitative as well as quantitative similarities and differences in animal (including human) behaviour. Similarities by analogy must be distinguished from those based on evolutionary kinship; differences in degree, from those in kind.

Comparative psychology is in itself interesting, and has important applications in fields such as medicine and animal training. With the rise of an experimental comparative psychology in the latter half of the 19th century and its rapid growth during the

20th century, the study of lower animals has cast increasing light on human psychology, in such areas as the development of individual behaviour, motivation, and the nature and methods of learning. Other animals are easier to obtain in numbers and can be better controlled under experimental conditions than human subjects. Much can be learned about man from lower animals; moreover, the discovery of differences illuminates the similarities.

The common-sense tendency to endow lower animals with human capacities always has been strong. People often talk to them as though dealing with human beings. An extreme development of this tendency is the doctrine of metempsychosis (*q.v.*), holding that after death the human soul may reside in another person or lower animal.

In recorded history two different views have developed concerning man's relation to the lower animals. One, termed for convenience the man-brute view, stresses differences often to denying similarities altogether; the other, the evolutionary view, stresses both similarities and differences. Aristotle formalized the man-brute view, attributing a rational faculty to man alone, lesser faculties to the animals. On the other hand, from the 19th century Darwinism considered man a highly evolved animal, the modern view in science. Scientific evidence indicates that continuity in the evolution of organisms provides a basis for essential psychological similarities and differences among lower and higher animals.

This article is organized as follows:

I. Methods

1. Gathering Evidence
2. Interpreting Evidence
3. Anthropomorphism
4. Adaptive Behaviour or Purpose
5. Morgan's Canon
6. Objective Attitude

II. Psychological Standing

1. Psychological Levels
2. Consciousness
- A. Critical Points of Change in the Animal Series
 1. Protozoans and the Concept of Simplicity
 2. Psychological Limitations of Lower Invertebrates
- B. Cephalization and Centralized Control
 1. Functions of a Simple Brain
 2. Advances in Orientation
 3. Simple Learned Modifications

III. Evolution of Behaviour

1. Behaviour and the Processes of Evolution
2. Evolution, Structure, and Behaviour
3. Ancestry and Behavioural Resemblance
4. Phylogeny, Ontogeny, and Instinct
5. Factors in Rhythmic Behaviour
6. Ontogenesis of Vertebrate Behaviour
7. Maturation
8. Factors in Organization
9. Nervous Systems and Behaviour

IV. Psychological Superiority of Mammals

- A. Development of Behaviour in Mammals
 1. Maturation
 2. Genetics of Behaviour
 3. Influence of Experience
 4. Drive and Motivation
 5. Sensitivity and Perception
 6. Sensing *v.* Perceiving
 7. Simplest Perceptual Relationships
 8. Contrasts in Perceptual Ability
- B. Learning Ability
 1. Varieties of Learning
 2. Experience and Abilities in Learning
- C. Intelligent Behaviour
 1. Criteria
 2. Insight
 3. Relative Aptitude for Indirect Solution
 4. Reasoning as Reorganized Learning
 5. Relative Independence of Stereotypy
 6. Representation as a Secondary Factor in Reasoning

V. Man Compared with the Lower Animals

1. Time, Reasoning, and Foresight
2. Verbal Language and Communication
3. Conceptualization and Intelligence
4. Emotion
5. Aesthetic Perceiving
6. Personality and Abnormal Behaviour
7. Contrasting Social Patterns

I. METHODS

1. Gathering Evidence.—Fact gathering requires special training in scientific methods, for which personal feelings are no substitute. All reports, whether anecdotal or arising from laboratory experiments or from studies in natural habitats, must be evaluated for reliability according to what conditions prevailed and what precautions were taken against error in gathering facts.

As in science generally, the soundest method of study at hand is used. An observer of nesting behaviour in birds constructs a hideout or blind to minimize disturbances resulting from his presence. Binoculars, a camera, and special mechanical means for recording the bird's reactions may further increase reliability.

In the laboratory it is possible to regulate general factors such as age and physiological condition of subjects, to exclude disturbances, to change environmental conditions or keep them constant, and to introduce apparatus designed to ensure accuracy. Thus animal psychology has employed the maze method as one means of testing learning, special problem boxes to test intelligent behaviour, and a variety of other techniques to increase the significance of the evidence.

Problems presented by a maze, for example, are not unlike those encountered by an animal finding its way under natural conditions. Such situations, when adequately planned and standardized, can meet the criteria of validity (*i.e.*, relevance to the behavioural variables in question) and reliability (*i.e.*, consistency of results in repetitions).

2. Interpreting Evidence.—Late in the 19th century, in Berlin, Ger., a horse named Hans became renowned for purported mathematical abilities. When a problem was written on a blackboard before him, Hans, by tapping first with right forefoot and then with left, indicated the answer in digits and tens respectively, with such success as seemingly to support the owner's claim for calculations by the horse. Although skepticism was expressed by many, and some alleged trickery, others asserted that the owner must be honest and his claims therefore valid. Scientific surveys of the case, particularly by the psychologist O. Pfungst, supported the following analysis. The horse performed well whether the owner was present or not, apparently ruling out trickery due to the owner's presence. But Hans failed unless the trainer or someone else was present who knew the answers; hence success depended somehow on human influence. The fact that the horse failed when blindfolded excluded telepathy while indicating some other effect from persons present. Observing the audience carefully, the psychologists found that when a problem was written down, someone who knew the answer would bend forward very slowly, whereupon the horse would begin tapping. After the correct number of taps, the person would relax, usually with a little movement, as of the head, and the horse would stop. Slight movements of this kind were known to psychologists as inadvertent activities accompanying acts of close attention. Pfungst concluded that, without the owner's knowing it, the horse had learned to start and stop his taps according to appropriate sensory cues. The horse was equally successful whether the problem was in simple arithmetic or in calculus; also, his responses to easy and to difficult problems alike often were incorrect by only one or two digits, suggesting a direct control of the tapping that could operate now early, now late, rather than mental operations. Hans typically began tapping mechanically when all was ready, without even looking at the figures.

This case brings out some important principles of interpretation in comparative psychology. The investigator selects a likely hypothesis, but considers it tentative until it is supported by experiments in which all factors of possible importance are controlled. (In the Clever Hans case, the roles of sensitivity and habit in the horse, the factors of audience knowledge and of subtle motor aspects of attention, and still others were tested.) After his experiments, the scientist sifts and organizes the available evidence, using mathematical techniques when possible, to find what theory best fits the facts.

These safeguards are essential, whatever the nature of the behaviour problem. Yet Clever Hans mistakes still arise, comparably obscuring the nature of the animal's accomplishment, when

bias or preconception blunts the objective planning of research.

3. Anthropomorphism.—People tend to ascribe human attributes to other beings. Thus it is said that moths and other insects fly to the light out of curiosity; the rattlesnake sounds its rattle to warn intruders; pets and domestic animals are noble or sly and deceitful according to conditions; and so on. The practice of interpreting behaviour on the basis of selected stories is called anecdotalism. Thus Plutarch in ancient Rome, Jean de La Fontaine in 17th-century France, and countless other writers have busied themselves in narrating stories about mental feats in lower animals.

Although valuable literary works may be created, such anthropomorphic literature risks fundamental flaws. It typically involves the implicit assumption that any person is likely to be well acquainted with his own behaviour and thoughts (for comparison with those of lower animals). There is, however, much psychological evidence to the contrary. No person, however well intentioned, should rest content with just one or a few outstanding examples as the basis for interpretations of what animals do. A single observation is low in reliability, as is any number influenced by prejudices and preconceived notions.

4. Adaptive Behaviour or Purpose.—Unnecessary complexities often arise because of the interpreter's point of view. Under normal conditions behaviour generally conforms to what might be called "appropriate" or "best" in the given situation. Thus the Venus's-flytrap closes its hinged leaf when a fly alights, but not when stirred by a breeze; the scallop closes its shell as its common enemy, the starfish, approaches; the octopus frequently remains secluded until its prey, the crab, is nearby; the chimpanzee may attain food out of reach by piling boxes. Acts that seem well adapted to particular conditions are often described as purposive. But this generalization of purposiveness in behaviour raises difficulties.

The above cases are typical—what can be said about them? First, these acts occur as described: the reports are reliable. Also, the acts have in common the characteristic of being adaptive. As a result of natural selection, behaviour tends to be adaptive to the typical species environment, promoting individual adjustments to the species habitat and furthering species survival. Although many theorists mean only this when they use the term purposive, a distinction seems desirable between what is adaptive and what is purposive.

H. Driesch and W. McDougall are associated with a view in the nature of teleology (*q.v.*) that all behaviour of the type termed adaptive is endowed with directive forces comparable with human volition. When a man behaves purposively, he strives for an end he anticipates or expects. If all animals actually performed their adaptive behaviour on the basis of such a process, the theoretical problems of comparative psychology would be relatively simple, for the same type of solution would apply to all cases. But the danger exists that the teleological type of explanation may arise from the theorist's preconceived notions rather than from reliable supporting evidence.

5. Morgan's Canon.—A useful rule in scientific interpretation is the principle of parsimony, which may be stated as follows: of alternative explanations for a given phenomenon, choose the simplest, that requiring the fewest assumptions, provided it meets the facts adequately. This principle was stated by C. L. Morgan (*An Introduction to Comparative Psychology*, 1894) as follows: "In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty, if it can be interpreted as the outcome of the exercise of one which stands lower in the psychological scale."

The purposive type of explanation for the above examples would be that the Venus's-flytrap needs food, hence closes when touched by insects but not by inedible objects; the scallop recognizes the starfish as an enemy and closes its valves to avoid destruction; the octopus hides so that its enemies cannot see it and its prey may come close; the chimpanzee stacks boxes in order to obtain suspended food. Although at first sight these purported explanations all may appear simple, actually they are all complex and no one of them should be adopted until alternatives have been con-

sidered in the light of Morgan's canon. Each hypothesis assumes that the animal anticipates the consequences of one action or its alternative (*e.g.*, the scallop anticipates death if it does not close, and can weigh the possibilities somewhat as a reasoning man might). Humanlike capacities, such as understanding meanings, anticipating results, and choosing between alternatives, are thereby implied by these purposive explanations. The evidence, however, favours a purposive explanation in only one of the described instances, the case of the box-stacking chimpanzee. W. Köhler and others have shown that this animal seems to anticipate success when jumping from the ground to suspended food, to understand the significance of a box as a means of reaching food, and to solve problems by reasoning. Conversely, to account for the flytrap's reaction, only a simple reflexlike reaction to stimulation need be assumed, for the leaf closes its two hinged halves automatically on any contact sufficient to bend its sensitive trigger hairs at their basal joints. As for the scallop, experiments show that it closes in response to any sufficient chemical effect, as to starfish broth released in the water nearby, but not to a starfish presented behind glass (visual control). In the case of the octopus, an intent to hide is excluded by J. A. Bierens de Haan's finding that the animal slips between plates of glass, where it remains in full sight, as readily as between pieces of slate. The simpler explanation consistent with the data is that the octopus comes to rest when its body touches between surfaces, not because it understands hiding.

These cases illustrate the value of investigation in testing assumptions and reaching an adequate explanation. Too frequently a purposive account merely names the gains of an activity (*e.g.*, protection, food) without clarifying the process involved. But a name alone is no explanation, and may in fact suggest an unwarranted interpretation. Adaptive acts must be explained through evidence from investigation rather than by analogies between lower animals and man, for activities which lead to similar adaptive results (*e.g.*, both the leaf closing of the flytrap and the box stacking of the chimpanzee are food-getting behaviour) may be very different psychologically.

6. Objective Attitude.—Early in the 20th century the view gained ground that careful experimentation on behaviour under controlled conditions should improve psychological theories. A chief contribution of this movement to comparative psychology was its emphasis on objective as against subjective procedures for evaluating and comparing the psychological resources of different animals. To appraise any animal activity, the psychologist must consider its nature and adaptive value, the situation, and what factors in the species' organic makeup and in individual experience may have contributed.

The first task in comparative study is to discover the characteristic behaviour in each animal type; the next is evaluation. It is not sufficient to assign positions in a series, classifying some animals as inferior and others as superior; the presumed inferiority or superiority must be clarified through comparisons. Neither the stability nor the adaptive efficiency of behaviour are as indicative of superior psychological status as are modifications of behaviour to fit new conditions. The principal weakness of a topical study is the implication that functions such as "memory" are much the same wherever found. But any given function, such as learning, overlaps others and may also differ greatly according to the animal involved. Higher animals do not necessarily repeat the lower animals with the addition of certain new abilities. Rather than a recapitulation of the characteristics of lower animals in the higher, research discloses similar properties and others which assume new psychological significance. These matters may be illustrated by some outstanding differences observed among various types of animal.

II. PSYCHOLOGICAL STANDING

1. Psychological Levels.—The earliest formal statement of psychological levels was the scheme of Aristotle, endowing plants with a nutritive faculty alone, the lowest animals with sensory faculties also, higher animals with an appetitive faculty also, and man alone with a rational faculty. Descartes' ideas embodied a sim-

pler scheme: a lower level of animals, viewed as automata, and man as the sole rational being, on a higher level. In 1905 R. M. Yerkes differentiated levels on the basis of functional criteria and experimental evidence: (1) discrimination, a general form of response, shown by lower invertebrates; (2) docility, or modifiable reactions, seen in rodents; and (3) initiative, or response variability, observed in primates.

Such systems are speculative and may restrict the experimenter's viewpoint; they tend to oversimplify and encourage categorical interpretations of animal activities. Distinctions of psychological levels are rejected by those who believe that functions such as perception and learning exist in all animals. Experience, however, favours the concept of psychological levels to represent transitions from lower to higher psychological stages and to summarize knowledge of animal relationships, as long as complete discontinuities from level to level are not assumed.

2. Consciousness.—When we see another individual behaving more or less as we do under comparable conditions, that being (whether man or lower animal) is often assumed to have an experience similar to our own. Thus Montaigne, from occurrences such as the starting and barking of dogs in their sleep, thought that they must have imagination. Late in the 19th century the prominence of introspective methods in psychology encouraged a strong tendency to analogize consciousness. This tendency weakened after the failure of attempts to use consciousness as a criterion of animal mentality. The chief objections were that introspection, considered low in validity for human psychology, could not be valid for lower animals, which lack speech; and that if inferences concerning the subjective aspects of even the simplest mental states in man are held doubtful, little justification exists for applying the method of anthropomorphic analogy to lower animals.

A. CRITICAL POINTS OF CHANGE IN THE ANIMAL SERIES

1. Protozoans and the Concept of Simplicity.—Protozoans frequently are termed the simplest animals. However, H. S. Jennings and F. Alverdes found reactions of the ciliate *Paramecium*, for one, many and varied.

This organism is propelled forward, rotating about its long axis, by the beating of minute, hairlike cilia covering its ovoid body. When stimulated, it pauses momentarily, rotating narrowly or widely before continuing in a new direction, or backs away at an angle varying from acute to obtuse. Specific properties of the stimulus, particularly its intensity, may be critical; for example, weak contact typically elicits slight interruptions of forward movement, strong contact a pronounced backing reaction, and physicochemical properties of stimulation directly influence the extent and the duration of modifications in forward swimming. Although the protoplasmic changes underlying the many variations of ciliary stroke in these different reactions doubtless are biochemically complex, this behaviour is simple in the sense that it can be understood in terms of psychologically simple concepts, for a dictation of response by the physical properties of stimulation is the lowest order of psychological process.

Protozoan behaviour, nevertheless, is adaptive. When Jennings dropped a stream of carmine particles upon the disc of the attached trumpet-shaped ciliate *Stentor*, there occurred a series of reactions from a slight contraction of the oral disc to increasing general contractions which at length broke the animal free from the substratum. Jennings characterized these variable reactions to conditions of repeated stimulation as a series of trials. More objectively considered, such behaviour is the product of protoplasmic changes forced by repetitive stimulation. At first only the funnel end reacts; then as internal excitation spreads, the stalk contracts progressively toward its attached base. Behaviour thus changes successively through a progression of physiological summations producing new results as they reach more remote localities. Although the notion of trials emphasizes the adaptive aspects of these processes, it misrepresents the acts, which are forced by stimulation rather than arising as attempts of the *Stentor* to attain expected results.

This case illustrates how, in the simple psychological system of

the protozoan, variable reactions widen an animal's adaptation to surrounding conditions. Jennings demonstrated that *paramecia* collect around a drop of acid in their medium not through direct approaches to the acid but because they first swim readily into the area, then recoil from the acid-deficient border zone on each encounter. Since, in the ciliates, stimulus changes typically interrupt forward swimming differently according to their intensity and other physicochemical properties, the organisms thereby escape injurious agents in their environment. The adaptability of such reactions in protozoans stems from the persistence of variable swimming until conditions favour normal locomotion.

The status of behaviour changes in protozoans has been much discussed. As examples, amoebae, repeatedly exposed to bright light, put forth fewer pseudopodia before each further reversal of direction; *Paramecium*, introduced successively into a capillary tube from which it can escape only by doubling around, reverses with increasing promptness. Some writers consider such changes equivalent to learning in higher organisms, pointing to graphic records of reduced time or movement in these cases. Others, conversely, stress the limited duration of such changes in protozoans, also that many of them have been duplicated (as by chemical treatment) without putting the organism through trials. Thus, although F. Bramstedt reported that *paramecia* presented repeatedly with the stimulus pair of light (largely ineffective at first) and heat (generally withdrawn from) later withdrew from light alone, U. Grabowski found the behaviour a function of gaseous changes set up in the water during the trials. J. J. Best demonstrated the specific effect of temperature in sensitizing protoplasm to such agents as light. B. Gelber, however, reported an apparent instrumental conditioning of *paramecia* to approach an empty needle loaded with bacteria. D. D. Jensen has applied the term pseudolearning to such results, because controlled repetitions of the experiments demonstrate that such uncontrolled environmental factors as chemical traces can account for the changes. (See also PROTOZOA.)

2. Psychological Limitations of Lower Invertebrates.—Significant for judging the psychological level of an animal is its behavioural organization. Perhaps least endowed in these respects are low multicellular animals such as adult sponges. The sponge is a bottom-attached organism of the colonial type that feeds by filtering water drawn through chambers in the body wall. The reactions of sponges are simple, local, and sluggish. As G. H. Parker (*The Elementary Nervous System*, 1919) found, sponges lack integration among their parts except that resulting from structural unity and a crude transmission of mechanical impulses through certain primitive cells around the opening to the body cavity, combining sensory and motor properties. Such limitations may have characterized the early ancestors of multicellular animals prior to the appearance of neural tissue.

In the coelenterates a measure of integration exists in activities such as feeding, locomotion, and withdrawal from intense stimulation. This was found by G. J. Romanes and by Parker to be attributable to a nerve net, a continuous conduction network permeating the body wall and transmitting impulses from specialized sensory cells to specialized muscle tissue. Activities here, although far better integrated than in sponges, are still relatively sluggish and considerably below the level of cephalopods, for example. The low-grade centralization of the conduction system, as a major limitation, distinctly handicaps behavioural organization.

Activities are better integrated in echinoderms such as starfish and sea urchins. In normal behaviour, local activities are so effectively combined that J. von Uexküll, who investigated the neurophysiology, was led to characterize the echinoderm in action as a community of reflexes. In a reflex, stimulated sensory cells transmit impulses to association cells in the neural system, which arouse muscular contractions. Thus, the tube feet, small fingerlike muscular structures capable of adhering to the substratum by their terminal sucking discs, when stimulated lightly, bend toward the affected side through one muscular action; when stimulated intensely, they bend away through another action. An appreciable local autonomy is indicated by the fact that the characteristic echinoderm structures, tube feet, pedicellariae (nippers), and spines,

when cut from the animal and appropriately mounted, react to stimulation much as before. To be sure, throughout the animal series, reflexlike actions enter into the normal functioning of internal organs (e.g., the vertebrate heartbeat), controlled reflexly in a more or less automatic manner. Even in mammals, reflexes may intervene in general behaviour, as in scratching or sneezing, but with a very different significance than in lower invertebrates. For the latter, the community-of-reflexes concept has some validity for a behaviour in which somewhat autonomous local activities are combined differently according to the conditions of arousal.

Yet the behaviour of lower invertebrates such as coelenterates and echinoderms is more than a chain-reflex combination of functions, as sense organs and motor structures are linked functionally together by the nerve net. Thus, soon after pedicellariae have caught prey, the tube feet extend, attach, and "walk" the object toward the centrally located mouth, which meanwhile everts and folds around the victim. The simplest nerve nets (as in the coelenterate *Hydra*) have a minimal polarization related to the growth gradient, and conduct according to the strength and localization of external stimulation without strict directionality. Such nerve nets exemplify the function of primitive conduction systems, joining local operations without specifying the behaviour pattern. Although in mammals nerve-net functions are visceral and local (as in coordinating intestinal activities in digestion), in the lower invertebrates nerve-net correlation is the main agency unifying behaviour.

Echinoderms advance materially in behavioural organization as compared with coelenterates. A more versatile integration of local function exists in the righting response, aroused when the animal is turned on its back. In the inverted starfish, with previous stimulation and handling equalized, two or three rays twist about, and when the ventral surfaces of these rays touch the ground, tube feet progressively closer to the central disc attach. These rays thereby swing the body of the starfish, overbalance, and right it. For this reaction to occur, it is necessary that the rays of one side become dominant.

A. R. Moore demonstrated that this organization normally depends on impulses through the nerve ring interconnecting the radial nerves of the five arms. When this nerve ring is sectioned, all rays attach, behaviour is uncoordinated, and righting occurs slowly and abnormally. Through nervous impulses, therefore, the normal unitary behaviour of echinoderms involves the temporary subordination of certain local activities to others dominating general action. The studies of J. E. Smith on the starfish nervous system reveal new complexities, including ganglion-cell mechanisms involved with the nerve net, advancing behavioural organization beyond that of the coelenterates.

An improved organization of behaviour thus enters with the subordination of local, reflexlike functions to wider patterns, as when scratching is inhibited as a dog sees food. The local activities themselves are then not only more elaborate and diversified, as in the reflex-cleaning activities of insects, but also better related to other behaviour. Echinoderm behaviour is more than a community of reflexes; sponge behaviour is far less.

Although echinoderm adaptive activities are impressive, they are sluggishly performed and their level of organization should not be overestimated. Jennings endowed the starfish with the ability to learn, on the basis of tests in which individuals shortened the time required to right themselves. One pair of rays was prevented from attaching by a glass rod used to disengage the tube feet from the substratum, and after 180 trials these arms attached less readily than before the trials. Although Jennings interpreted this as habit formation, Moore produced similar results merely by rubbing the tube-foot surfaces of particular rays with a glass rod or treating them with weak acid. He therefore attributed Jennings' results not to learning (i.e., changes in central organization through experience) but to injury of restrained arms through continuous friction with the rod which altered sensory and motor function in further trials. These results are therefore equivalent to the impairment of action through motor fatigue, or its reduction through sensory adaptation or injury, not ordinarily classed as learning in higher animals.

B. CEPHALIZATION AND CENTRALIZED CONTROL

1. Functions of a Simple Brain.—Improvements in both organization and capacities of behaviour appear in worms, mollusks, and particularly insects. Basic advances are illustrated in a simple form in the earthworm. Whereas echinoderms are radially structured, and any of the body sections can lead in locomotion or other activities according to circumstances, worms have an anterior specialized end, which is not only the most sensitive and mobile of all body sections but also the dominant one by virtue of a superior ganglionic centre (brain). Cephalization, or head dominance, improves organization basically, widens the range of environment and action, and carries behavioural organization beyond the conditions prevailing in protozoans, coelenterates, and echinoderms. The significance of specialized head receptors and a brain for efficient behaviour in a marine worm is indicated, after the brain has been destroyed, by irregular crawling about, by turning much more clumsily on contact, and by burrowing less readily than a normal worm. The animal after operation cannot extend from its burrow (on chemical stimulation) and seize prey as does the normal individual. Removal of the worm's brain, although not preventing normal reactions altogether, materially reduces their directness and precision. This is therefore a primitive type of brain, a collector and a transmitter of impulses from the most sensitive parts of the organism, presumably also an amplifier, but not a major organizing centre. The brain of insects, in contrast, is an indispensable organizing centre. Although a bee or ant with its brain destroyed may stagger about for a time before dying, with a degree of locomotor coordination, only scattered reflex acts such as stinging occur and the complex normal repertory (e.g., foraging, building) is gone.

Local functions such as feeding and locomotion in higher invertebrates, as demonstrated particularly in the work of K. Roeder and H. Mittelstaedt with certain orthopterans, have a degree of autonomy and of complexity far above that of corresponding functions in the vertebrates. In cockroaches, for example, after removal of the head, conditioning of isolated ganglia is still possible, modifying control over actions such as leg movements. Comparable alterations in local actions seem unlikely for vertebrates, in which brain and higher centres have a different and more essential role in integration.

2. Advances in Orientation.—Regulation of locomotion and way finding under changing external stimulation improves in worms, mollusks, and arthropods over its status in lower invertebrates. J. Loeb emphasized that the evolution of a specialized anterior and bilateral symmetry opens the way for new patterns of orientation in space. These improvements admit more appropriate changes in adjustment to external stimulation, as when an octopus turns toward the side on which a crab is seen but does not pursue if the object moves too swiftly. At this stage the crude energetic properties of stimulation are dominant, as when a worm or snail approaches the source of a weak chemical but withdraws from the source of an intense stimulus, with variable behaviour at intermediate concentrations. The directive effect of stimuli of different intensity acting on receptors of the opposite sides of the body is shown by experiments in which a fly with its right eye covered turns toward the right under strong light but toward the left under weak light.

Progress in the organization and variability of orientation is indicated from the worms to insects, depending on the complexity and specialization not only of receptors but also of the central nervous system. The octopus, for example, has eyes much better fitted than those of marine worms for general vision, with accommodation to distance, and can inhibit its dash at a crab until within range. Social insects such as ants and bees have compound eyes, admitting versatile reactions to visual movements as well as movement with reference to changing visual stimuli. Although the evolution of orientation in space involves receptor specializations, advances in this capacity are especially correlated with the nervous system. Operative longitudinal sectioning of the brain introduces progressive impairments in the orientation of animals from worms to insects. J. Z. Young demonstrated that the octopus, through experience, can master conditioned responses to a crab, or to visual forms experienced with food. In such functions the octopus, far

superior to worms, loses correspondingly much more through brain operations. Although in the lower invertebrates quantitative aspects of stimulation such as intensity, size, and rate of change basically control the timing and precision of orientation, in the cephalopods and insects, as compared with the worms, the patterns not only become more complex but also more changeable according to experience.

3. Simple Learned Modifications.—Evidence offered for learning in protozoans (as noted earlier) seems inadequate. The claims of Jennings and others for learned modifications in such invertebrates as coelenterates and echinoderms have been disputed by Parker and others on the grounds that the changes rest on altered peripheral processes (as in sensitivity or in muscular function) rather than on alterations of central neural functions. Results obtained by H. B. Hovey might be taken to suggest that flatworms are the lowest invertebrates capable of conditioned-response learning. Hovey found that, although light ordinarily keeps the marine flatworm *Leptoplana* active, presenting light together with head contact (which stops movement) changed the worm's responses within 20 five-minute periods to a stoppage of movement in light. R. Thompson and J. V. McConnell attempted a correction of Hovey's choice of stimuli in work with the terrestrial flatworm *Dugesia* using four main groups of subjects, with light the conditioned stimulus and shock the unconditioned stimulus. The investigators reported a conditioned reaction to light depending upon its association with shock. E. S. Halas and others, however, could not confirm the results in attempted replications. Jensen has criticized the experiment, centring on the fact that the groups were not adequately compared in terms of the effects of light and shock alone or in combination, suggesting that shock itself may have been the critical factor.

Better evidence for conditioned learning was obtained by M. Copeland, who trained the marine worm *Nereis* to emerge from a tube in response to light or to dark, whichever had been paired with meat juice in training. A more complex habit was acquired by earthworms in Yerkes' experiment, in which turning to the left at a T junction led to electric shock, to the right into a dark box. Within 160 trials some of the worms regularly turned right on reaching the junction. This habit does not depend on specific sensory or muscular changes; when L. Heck reversed the electrodes and dark box after the habit was learned, worms that required more than 120 trials to acquire the right turn now reversed it within 75 trials. Such modifications indicate a basis in central nervous organization rather than in peripheral function. No learning comparable to this adjustment has been demonstrated in coelenterates, echinoderms, or flatworms.

The organization of behaviour is greatly enhanced by a potential for learning. Some worms, through learned changes, can alter their normal activities, though not as much as higher invertebrates. In learning, illustrated by the conditioned response, through experience a specific reaction is given to a stimulus previously incapable of eliciting such behaviour. In Copeland's experiment, light (the conditioned stimulus) initially did not bring the worm from its tube. Meat juice (the unconditioned stimulus) was effective, however, and pairing these two stimuli brought for light a new control over reactions. In the worm's T-maze behaviour, through comparable changes, stimuli near the junction control the right-turning reaction, rendering contact with the electrodes unnecessary. An adequate basis for such changes is afforded by a central nervous system with ganglionic centres and interconnections admitting appropriate new sensory-motor organizations. The mere presence of ganglion cells is not enough, for the starfish despite such equipment seems incapable of such learning. In arthropods, neural evolution

admits further advances in learning capacity. See also NEUROLOGY, COMPARATIVE.

III. EVOLUTION OF BEHAVIOUR

1. Behaviour and the Processes of Evolution.—Modern science interprets behavioural differences in animals, from protozoans to man, as the outcome of long and complex evolutionary processes. The role of behaviour in evolution is by no means obvious, however, as inferences from fossils must be validated by evidence on the relationships of structure and behaviour in existing organisms and these, rather than forming a linear series, represent different branches of a complex related system of which many sections have vanished. Also, the relations of structure and behaviour not only resist unraveling but seem to have very different properties in the principal types of existing animals. Despite these and other obstacles, behaviour has clearly evolved.

There is little question that behaviour has played a critical and major role in organic evolution. Efficiency in widely different activities, from foraging to defense and shelter getting, has much bearing on the success of reproductive processes and hence on species survival. In many ways, behaviour must have influenced intimately the selective processes underlying evolution.

The initiatory mechanism for evolutionary change, biologists conclude, involved mutations in the chromosomes, effected through the action of radiation on the organism through chemical, mechanical, or other extrinsic agencies. Mutations (see EVOLUTION, ORGANIC) may have involved any aspect of structure in the organism, thereby altering behaviour in diverse ways from the specific to the general. The evolution of mammals must have involved (far more extensively than that of invertebrates) mutations basic to the development of structures capable of complex and plastic relationships with function and behaviour. As new mutations affected existing physical structures, behaviour diverged with increasing frequency from ancestral patterns.

According to conditions, success in behaviour affecting reproduction must depend on what responses are made both in everyday existence and in critical or marginal situations. Because behaviour results from the interactions of functional systems (sensory, neural, secretory, motor, and others), a mutation affecting structure locally can often influence functions in the organism as a whole. For example, a more sensitive eyespot may improve directed responses to light so that orientation and foraging become more efficient, and adding a lens to the system widens the range and efficiency of adaptation still more.

Mutations thereby open the way to specialization in behaviour, favouring the occupancy of species-typical habitats (niches). Within any period, the relative success of behaviour affecting reproduction determines which strains and species can adapt to appropriate niches and survive and which types perish through mutations leading to detrimental or inefficient behaviour. As accumulating mutations favour diversity, successful animal types tend to expand into lineages differing increasingly in their adaptive patterns. The survival of a species then depends on its possessing a set of genes contributing under appropriate conditions to the development of a behaviour pattern adequate to maintain the reproducing population in its species niche.

2. Evolution, Structure, and Behaviour.—Structure, physiology, and behaviour are interrelated, although differently according to phyletic level; hence the role of natural selection may differ from level to level. The progress of evolution is not correctly described as a process adding new properties to the old, but rather as one transforming the old in conjunction with the appearance of new properties in new phyletic settings. The fate of species and species relationships in evolution depends primarily on the relative efficacy of structures rather than on purposive considerations, which involve a basic misconception of species-typical acts and their dependence on structures. Thus a dragonfly that ordinarily lays eggs on water may lay them on a freshly tarred roof, not by mistake, but by responding to the sensory characteristics of a shimmering surface.

At early stages in evolution, structure bears rather directly on behaviour, favouring stereotyped patterns. Invertebrate activi-

At first, light is ineffective, but after having been combined several times with meat juice, light alone brings the worm from the tube

ties thus are dominated by the functional characteristics of specific sensory, motor, or other equipment or of particular physiological conditions. These relationships can be misunderstood, particularly when they are complex. Thus J. H. Fabre believed in an "inflexibility of instincts" in insects (attributed to inherited nervous patterns), arguing from cases in which performance presumably could occur only once, as he reported the callow mason bee able to escape only once from the paper cell of pupation. But L. Verlaine found that in this case the critical matter was strength of the jaws, for when the cell wall was not too tough, the bee could escape more than once even on the first day. Dependence of behaviour on particular organic conditions is illustrated by the fact that spiders can repair their torn webs or not according to the supply of secretion in their different silk glands. However, structure is much less simply related to behaviour in mammals.

Throughout evolution, and particularly at times of crisis and other turning points, evidently mutations were favoured that increased the complexity of structures basic to functional relationships, promoting more versatile environmental adjustments. Significant sequences thus are indicated, as when local specialization of the skin of early vertebrates added a lens to the primitive eye, increasing the efficiency of space perception, which increased still further when specializations in retina, eye muscles, and brain admitted binocular vision and an augmented depth effect.

New adaptive levels were achieved in evolution not just through added complexity of existing structures affecting function but through qualitative changes as well. In a succession of adaptive radiations from the acellular to the multicellular, and from the primitive vertebrate ancestor to the reptilelike mammalian ancestor, basic changes occurred in the conduction system with important consequences for behavioural organization and for new behaviour. The result presumably was not so much that mechanisms of lower levels were repeated on higher levels as that they were modified in relation to the new context. Accordingly, it is probable that in vertebrate evolution from fish to man the "old brain" was not merely retained in a more complex form, but was progressively repatterned correlatively with increasing cortex. In mammals, as compared with invertebrates, not only are structural mechanisms much more versatile in their functional relationships but limitations of action by specific structures relax increasingly, widening the breadth and plasticity of behaviour in its bearing on species adaptation.

3. Ancestry and Behavioural Resemblance.—In the animal series, behaviour patterns tend to exhibit similarities in proportion to the degree of phylogenetic relationship and dissimilarities in inverse proportion. All animals are similar in the sense that behaviour is adaptive and that each behaves generally to attain beneficial and escape injurious conditions. This similarity depends on the fact that all species have mechanisms favouring approach to stimuli of weak intensity, withdrawal from stimuli of strong intensity. In phyla from protozoa to man, however, these reactions differ in structural bases and in ontogenesis.

In principle, existing animals do not form a linear series but represent the termini of a multibranched system among which exist discontinuities (e.g., insects, birds, mammals) and continuities (e.g., reptiles, birds). Roughly in correspondence with ancestral affinities, increases are found in the degree of structural homology and of similarity in the functions to which structure is basic. An example is seen in the front limbs of vertebrates, all significantly involved in directional control. Superimposed upon such general patterns are disparities among groups that have taken different directions of specialization, as that between fish and birds in the different orientative functions of the pectoral fins of the former and the (homologous) wings of the latter.

Striking differences among the specific adaptive patterns of surviving phyla show that the principle of continuity in evolution must be qualified in view of different branch lines in ancestry. For example, arguments, on grounds of evolutionary continuity, that a learning capacity exists in protozoans analogous to that of mammals oppose the fact that since unicellular and multicellular animals diverged in remote geologic times they have differed progressively, and the advent of mechanisms basic to the learning

abilities of multicellular organisms may well have postdated the common ancestry.

Because structure may influence function very differently on different animal levels, both in the relative directness and in the nature of its effect, the principle of structural homology (i.e., basis in common ancestry) cannot be generalized directly to behaviour. A different reservation concerns resemblances through convergence, or adaptations evolving independently, whereby similar niches are occupied or similar activities arise. Owls and bats, for example, have analogous adaptations for flight and the nocturnal capture of prey; termites and ants have similar patterns in nesting and other social activities.

O. Heinroth, particularly, and later K. Lorenz stressed behavioural characteristics as an additional clue to evolutionary relationships. Thus similar activities in closely related species often exhibit gradations evidently corresponding to the relative recency of the species. For example, in the mating patterns of empid flies prior to coupling, in one species the male presents to the female a freshly killed insect, in another species he presents the booty within a cocoon he has spun, and in still another he presents only an empty cocoon. The last pattern is presumably the most recent.

Striking similarities, not convergences, are often found between related species living in widely separated habitats, as, for example, both English and South American thrushes line their nests with mud. Comparisons are complicated, however, in the similar patterns of related species which are sympatric (i.e., live in the same habitat) by the rise of specialized differences through competitive processes influencing natural selection. Thus two closely related species of doryline ants in the genus *Eciton*, sharing the same New World tropical forest habitat, differ strikingly in the patterns of their predatory raids, with colonies of one species pillaging in large swarms, colonies of the other in complex systems of columns. These species also differ in the booty they capture, with the first taking mainly hard-bodied arthropods, the second, soft-bodied brood of various insects.

At times, however, as when selection pressures are not intensive, sympatric and closely related species may be more alike. For example, in contrast to the *Eciton* species cited, surface-adapted doryline species of the Old World genus *Aenictus* resemble one another closely in aspects of behaviour in which closely related *Eciton* species differ.

4. Phylogeny, Ontogeny, and Instinct.—The traditional view that ontogeny recapitulates phylogeny, questioned for structure by G. R. de Beer and others, is even more doubtful for behaviour. What individuals in each species inherit are their chromosomes, influencing ontogeny in species-characteristic ways provided development occurs under species-typical conditions. Under other extrinsic conditions, different phenotypes (developmental forms) appear, diverging from the species-typical pattern not only structurally but often also behaviourally. Species-typical behaviour patterns, considered in relation to species genetics, constitute the problem of instinctive behaviour.

A useful way of stating this problem is to say that although heredity influences all behaviour in all animals, its influence is more direct in more primitive animals than in the more advanced and seems to be very different on different phyletic levels. This interpretation contradicts the traditional view that the "instinctive" and the "learned" may be clearly distinguished in animal behaviour, with the latter increasingly prominent in higher animals. It is more likely that behaviour evolves through new and increasingly complex reorientations, with the old rebuilt and extended in terms of the new, than through the replacement of the "innate" by the "learned."

On each phyletic level, striking differences appear in the relationships between genes, species-typical structures and physiology, situational conditions at successive developmental stages, and the predominance of species-typical behaviour as against genotypical patterns. In the sense that the activities of invertebrate animals are more directly dominated by structure than are those of mammals, invertebrate behaviour is more instinctive. Accordingly, agencies mediating among genes, organic mechanisms, and behaviour are fewer, with less numerous and less involved interrelation-

ships in protozoans and sponges than in insects, with insects in turn below rodents and rodents below primates. In this succession, the role of heredity in behavioural development is not decreased, but rather becomes increasingly indirect and plastic as further and more diverse intervening variables are added. Consequently, contrasting behaviour patterns arise which are not only increasingly complex but also qualitatively progressive. For understanding these differences, the classical nature-nurture dichotomy is not only too simple but also misleading. Psychological superiority must have emerged in higher animals not through less nature and more nurture but through increasingly complex and qualitatively new properties of nature and nurture, inextricably interrelated in development in ways characteristic of the level.

As an example, function varies strikingly with age both in invertebrates and in mammals. In honeybees, G. Rösch attributed such differences to growth-conditioned organic changes. Young workers just emerged from pupation tend to specialize in feeding larvae, but about the 15th day, when the salivary glands atrophy, they turn mainly to building. This activity falls off about the 25th day, when the wax glands end their active phase, and is replaced by foraging. Such activity successions are not uncommon among social insects. For honeybees, however, E. Lindemann stresses the condition of the colony as a major factor influencing function in workers of all ages. A striking example of functional variations with development is found in such amphibians as frogs and salamanders which change radically in locomotion and other behaviour on leaving the aquatic for the terrestrial stage. In mammals, although ontogenetic changes in function certainly occur on a structural basis, behaviour develops much more subtly and indirectly in relation to structure than in lower animals.

It is therefore probable that the relationship of behaviour to survival, always important in evolution, is very different on various phyletic levels. As it is realized that assumptions of innateness in opposition to the acquired can explain no activity, increasing emphasis is placed upon the need for analytical investigation.

Although geneticists often state that the genes impose species-characteristic limitations on development, even in the 1960s this generalization lacked proof for behaviour. Actually, the influences of the genes are not direct or exclusive in determining behaviour in any animal but are exerted through diverse interrelationships between organism and developmental medium.

In all phyla, the functioning of organic factors underlying the rise of instinctive activities requires a developmental situation typical of the species. Frequently, certain conditions of stimulation (i.e., experiences) can be detected as critical for the development of the species-typical pattern. Thus J. E. Harker found that the normal day-night activity rhythm of the adult May fly does not appear when developing individuals have been subjected to continuous light or darkness but only when eggs or larvae have been exposed to at least one daily light-dark cycle. Comparably, species patterns such as the spinning of characteristic cocoons by caterpillars result from a close relationship between structural growth and features of the developmental situation. G. van der Kloot and C. Williams found that if a *Cecropia* larva cannot attain an upright posture against a support such as a twig, no cocoon is spun. Instead, the arrangement of the thread depends upon prevalent conditions. Thus, if the caterpillar ready to spin is put into a balloon it will line the interior surface with a sheet; if it is tethered to a peg, it will weave a cone around the peg. In the parasitic ichneumon fly *Nemeritis*, responses to the host upon which eggs are laid are influenced by larval experience, as such responses can be modified by changing the type of insect on which the individual feeds as a larva. Indicating the possibility that conditioning influences insect development, although in a secondary and obscure role, is evidence that the act of following odour trails arises in many ants on the basis of individual habituation to nest chemicals beginning as early as the period of larval feeding.

In lower vertebrates, species-typical behaviour such as mating and nesting have the characteristic of stereotypy, as in insects, but with a different aspect relevant to the level. The claim of Lorenz and others that certain critical acts called "instinctive

movements" arise through innate neural patterns determined isomorphically by the genes lacks effective support. Rather, Z. Y. Kuo, from his significant studies on pecking in chicks, concluded that intimate relationships exist between factors in growth and in the extrinsic situation.

Comparably, D. S. Lehrman found that important factors in the reproductive and parental behaviour of ring doves (beyond hormonal processes) are experiences with mates, incubating eggs, and young. E. Klinghammer and E. S. Hess reported that adult ring doves, after experience in incubating eggs, responded to hatchlings with feeding actions whether or not they had ever fed young. Although such patterns are species-typical and genetic, they are not predetermined neurally but result from a development in which organic processes interact intimately with situational factors.

5. Factors in Rhythmic Behaviour.—Behaviour rhythms of animals often parallel such events as the tides, day-night, and seasonal changes. O. Park recognized exogenous rhythms directly controlled by changes in the environment and endogenous rhythms that persist (often for some time) under constant conditions. Examples of the first type are the daily vertical migrations of marine zooplankton and the daily activity-quiescence routine of many grasshoppers, both mainly dependent on changes in light intensity. Examples of the second type are found in the day-night activity rhythms of shore crabs and the rhythmic activities of mussels in opening their valves and feeding at high tide and closing at low tide. The American crayfish *Cambarus*, as J. H. Welsh showed, can maintain such rhythmic actions as pigmentary changes as long as a few months under constant laboratory conditions. Evidence suggests that rhythmic physiological changes in eyestalk pigmentary processes, probably basic to such changes, are regulated by one or more hormonal mechanisms. Such endogenous regulatory processes (called biological clocks) have been demonstrated in animals from invertebrates to mammals; patterns as varied as the daily foraging of honeybees and man's rhythms of activity and sleep may be related to them. C. S. Pittendrigh represents the view that the frequencies of all biological-clock systems are innate, J. Calhoun that they are acquired; J. F. Brown suggests that they may arise through periodic external factors as subtle as changes in the earth's geomagnetic field. Seasonal changes in function and behaviour occur in many birds and mammals (see MIGRATION, ANIMAL; MIGRATION, BIRD; REPRODUCTION) and are often referable to physiological changes paced by such annual variations as daily illumination; puzzling cases include cave-dwelling bats and tropical birds in which an external basis is not apparent.

6. Ontogenesis of Vertebrate Behaviour.—Vertebrate behaviour seems to differ from that of invertebrates by virtue not only of a nervous system with a fundamentally different central pattern but also of organic factors underlying superior processes of perception and motivation. Although such functions as locomotion and equilibrium are well developed even in fish, in mammals the corresponding functions are more complex and more subject to variations according to the conditioning of ontogenesis.

An impressive contrast is that between altricial (blind-born) mammals and the precocial, which have sight soon after birth. The former (the rat is an example) are slower than the latter in structural maturation, and require a much longer time for behavioural development. The latter (illustrated by deer and other ungulates) can move erect soon after birth and show strikingly more rapid perceptual development. Such contrasts raise the question of how species-typical behaviour patterns develop in different vertebrates.

7. Maturation.—The concept of maturation, emphasizing the role in behavioural development of organic changes through growth and differentiation, has been focused by many upon the nervous system. In the study of G. E. Coghill on the salamander *Ambystoma*, successive stages in action were observed with correlated histological changes in the nervous system. In this tailed amphibian, an early nonmotile stage was identified when, with sensory surfaces still unconnected by nerves with muscles, the only action was an anterior bending to the side of direct muscular

stimulation. At about 30 hours of age, the head bent away from the stimulated side, paralleling the appearance of crossed nerve connections from the skin of the head to muscles on the opposite side. Then S movements of the body and, later, rapid swimming movements were correlated with further growth changes in the nerve tube. Coghill concluded that in the development of swimming in this vertebrate, the status of neural growth is critical. This conclusion found support in the research of L. Carmichael, who immobilized salamander embryos with Chloretone during the period in which swimming normally appears, yet found that when later released from the drug, these animals apparently swam as well as undrugged normal specimens. The conclusion that organic neural growth alone is sufficient for development of normal swimming in this amphibian is tentative, however, in view of evidence obtained by A. Fromme. His results indicate that opportunities for action and stimulation at certain stages in development also contribute to the swimming pattern, since embryos immobilized at those stages, when later released from the drug, swam less well than normals.

Maturation, as defined, seems basic to the behavioural development of lower vertebrates from fish to birds. The concept needs revision, however, in view of evidence cited below, bearing on the interaction of processes within the developing organism and between organism and external situation, characteristic of growth stage but extending beyond the specific bounds of growth and differentiation.

Although the development of behaviour patterns is often held to depend on an innate central neural control, this question is still controversial. Certainly, neural growth limits behaviour at any stage (e.g., the salamander cannot bend its head until crossed neural connections have grown). Other factors also are involved. The characteristic head lunge of lower vertebrates probably requires sensory maturation as well as neural maturation. Several such mechanisms evidently contribute to the adult lunging response, which, as in many fish, amphibians, and birds, occurs on weak stimulation. Thus the characteristic lunge is elicited by objects below a certain size if these are in motion at not too rapid a rate. Presumably, in lower vertebrates, tissue growth promotes adult patterns such as feeding and mating in discrete ways as through sensory-threshold factors in visual-movement responses. To understand the ontogeny of behaviour, however, the study must be broadened. Although, for example, gonadal hormones are basic to the appearance of mating behaviour in all vertebrates, evidence suggests that they may function in diverse ways beyond their possible neural effects, as by increasing local sensitivity.

8. Factors in Organization.—Against the traditional pre-deterministic view that instinctive behaviour is organized neurally on a native basis, the alternative epigenetic view holds that such behaviour develops through coordinations of many organic resources in the organism interacting with the developmental medium. Experience, definable as the effect of stimulation on the organism, participates in all development, and in diverse forms, including learning.

From the same genotype (see HEREDITY), variations in the conditions of development may result in phenotypes differing behaviourally as well as organically. Under different temperature conditions in development, M. H. Harnly obtained fruit flies which were flightless, limited and eccentric, or species typical in flight; and K. Moore in a comparable experiment obtained rats differing in both body form and learning ability.

For the organization of instinctive behaviour, evidence for invertebrates and for vertebrates shows that species-typical factors both of maturation and of experience in the standard developmental situation are essential. Certain poeciliid fishes, raised apart from species mates in neutral surroundings in which, for example, they never saw their own reflections from the water film or other surfaces, scored much lower than normals in mating tests at maturity. That the role of experience may involve learning in amphibian larvae is suggested by the fact that N. L. Munn found the early swimming stages of certain amphibians capable both of being conditioned and of learning a simple T-maze habit.

Although the roles of maturation and of experience are fused

in all behavioural development and resist experimental separation certain generalizations are possible. Thus organic factors seem relatively more determinative of behavioural development in lower vertebrates than in mammals. In the former, accordingly, naive responses to stimulation are less readily modified through experience than in the latter. The lizard *Lacerta*, studied by E. Ehrenhardt, gave its forward (feeding) lunge most readily to the movement of figures such as circles with even outlines, least readily to figures such as crosses with irregular outlines. When a circle was paired with a quinine-treated mealworm, a cross with an untreated mealworm, initial responses were virtually unmodified within 850 trials. In comparison, mammals such as rats normally change their initial responses readily according to the conditions of training. In lower vertebrates, discrete properties of the stimulus such as movement, size, and brightness characteristically dominate behaviour, evidently as a result particularly of correlated factors in sense organs and nervous system. N. Tinbergen and others use the term *releasers* for stimuli which typically elicit certain types of response; however, this concept has been criticized as too simple and as obscuring ontogenetic processes. For example, the gaping (mouth-opening) response of nestlings in passerine species such as thrushes is first aroused by mechanical stimulation, as by vibrations of the nest, later by the movement of any object (e.g., a black disk) of sufficient size presented above the nest edge. The facts suggest that, through conditioning, naive responses (e.g., to nest vibration) become attached to specific features of the external situation, such as first the parent bird's bulk at the nest edge, then the parent's head. The organization of such responses in birds is a complex matter in which experience may figure in various ways.

In this sense, birds have a far more extensive and complex repertory of instinctive, organically determined activities than have mammals. In the organization of activities such as migration, the role of maturation seems predominant, that of experience secondary. The investigations of W. Rowan and others show that the northward spring migration of birds such as juncos is set off through the excitatory effect of internal changes (e.g., pituitary and gonadal secretions) caused by a progressive increase in daily illumination. Evidence suggests that changes in organic condition may influence responses to environmental factors (e.g., temperature gradient, angle of the sun) governing the direction and course of migration.

Organic factors may have a comparable role in such behaviour as homing, as the use of mate and of nest to control direction of flight in homing pigeons attests. G. Kramer and others found that many birds, both in migratory and in homing flights, can maintain a constant or changing course through adjustments to the sun's position; F. Sauer reports similar responses to star patterns; G. V. Matthews and others suggest that for birds such as pigeons an internal time-controlling mechanism is basic to such functions. Much evidence indicates that in many birds homing and, in part, migration depend strongly upon experience with landmarks and topography.

The organization of species-typical activities such as pecking in fowl is known to have a complex individual history, starting in the egg. Kuo showed that, with maturation in neurosensory and muscular tissue, the embryo's head lunge to touch modifies under the influence of self-stimulation through its own actions. Crude conditioning processes are evident before hatching. Shortly after hatching, the significant activities of the head lunge, bill opening and closing, and swallowing are crude and essentially separate. Head lunging occurs, however, on the appearance of small, moving objects and (limited by maturational properties such as muscular strength) within a few days an organized and discriminative pecking at edible objects comes about. Thus it appears that whereas maturation dominates the development of individual components of pecking such as head lunge, experiential factors are required even for the early appearance of these components and are heavily involved in organizing the eventual efficient act. The influence of maturation is emphasized by the fact that, when chicks are kept in the dark and hand-fed for varying times after hatching, the process of improvement leads

sooner to efficient pecking than in normal chicks; *i.e.*, experience is more advantageous when strength and other organic factors have advanced. The influence of experience is emphasized by the fact that chicks fed artificially for longer than two weeks after hatching learn only with great difficulty to peck at food, since they have learned to feed otherwise than through pecking. The greater predominance of stereotypy in lower vertebrates than in birds seems attributable to the greater influence of experience in the behavioural development of the latter.

Life activities often are organized with reference to the environment into which the animal first emerged. Solitary wasps tend to establish adult burrows in the localities of their pupation; social insects generally have foraging territories centred on the fixed nest sites in which the workers developed. In invertebrates and lower vertebrates, such territorial attachments have a relatively simple behavioural basis; in mammals the fixation and use of territory in development is progressively more complex. Thus, for many birds such as the common tern and pigeon, A. T. Marshall and others indicate an attachment of the females first to nest site and environs, subsequently and secondarily to eggs and young. In chimpanzees and other subhuman primates, the territorial pattern common to everyday group routines seems often to have a history of many generations, made possible through involved processes of perceptual development and learning in each new generation of young.

9. Nervous Systems and Behaviour.—An important approach to understanding psychological differences between lower animals and mammals is through the role of the nervous system. Although in worms the appearance of a dominant brain permits definite advances over the radial pattern of the starfish, this centre is of a low order, mainly a transmitter rather than an organizer. Insects, much advanced in organization, still reflect a strong influence of sensory and other local components in behaviour.

As comparative neurologists have shown, the brain of lower vertebrates is not only more sparsely supplied with interconnections than is that of mammals, but the brain exerts only rudimentary control over lower centres and is not equipped to influence general behaviour in terms of changing stimuli. The forebrain (dominated by the principal sensory systems) and the midbrain (generally dominated by the visual system) are best equipped for integration of stereotyped behaviour. Such characteristics go far in accounting for the typical shortcomings of these animals in modifying naïve responses based on such stimulus aspects as intensity.

With the appearance of cerebral cortex, correlation among the principal centres of the vertebrate brain improves greatly. Cortex, although restricted in reptiles to a small area in the upper forebrain, and obscure in birds, covers the entire forebrain in mammals. Cortex interconnects the principal centres of the nervous system both directly and indirectly, admitting new types of organization which override specific sensory effects and local activities according to the animal's experience.

The evolution of cerebral cortex, particularly, seems to give mammals their psychological superiority. But, as K. Pribram has concluded, old-brain mechanisms also evolve, permitting an extension of their functions relative to the new brain. Thus, A. Brodal and others have pointed to the significance of the reticular formation, and P. D. MacLean and others to that of the limbic formation in ontogenesis; and D. B. Lindsley has suggested a major limbic role in mammalian perceptual development. The role of such brain-stem mechanisms in promoting plasticity in behavioural development seems to be much greater in higher mammals than in lower mammals and birds, far greater in the latter than in lower vertebrates.

The commissures, connecting the halves of the brain, parallel the cerebral cortex in their appearance and development in mammals. By testing split-brain cases, in which these connections have been cut, R. W. Sperry and collaborators have shown that the specialization of the two hemispheres for separate, complex acts, as well as their degree of integration in complex behaviour, increases in the cat, monkey, and man, in that order.

IV. PSYCHOLOGICAL SUPERIORITY OF MAMMALS

In mammals, from marsupials to man, the psychological limitations of lower animals are overcome progressively. Through more versatile capacities and better organization of behaviour, the world of the individual increases in content and in variety. The general superiority of mammals shows itself particularly in their resources for developing new behaviour. For example, reptiles, although they can be tamed so that they become docile, do not form attachments nor take the initiative in play with people, as do mammals.

A. DEVELOPMENT OF BEHAVIOUR IN MAMMALS

1. Maturation.—Correlated with the longer developmental period typical in mammals, their resources admit a greater weight for experience and a greater variety of behaviour appropriate to changing circumstances than in inframammalian animals. In general, higher mammals require a longer time than lower to develop. Accordingly, whole-body adaptive behaviour appears earlier in lower mammals, which often fend for themselves sooner after birth than the young of higher mammals. For example, the young opossum, just 12–15 days after development begins, crawls from the mother's cloaca over her abdomen to the pouch, moving along by a reflex hair-clutching and forelimb progression. At 60 days it leaves its nipple in the pouch on occasional excursions to the outside, where it runs and climbs about. The young of ungulates, such as the goat, are capable of upright progression shortly after birth; the human infant, in contrast, is incapable of self-progression until it crawls at about eight months of age.

Most mammals are relatively more immature at birth than the young of lower vertebrates, and hence cope less effectively with their environments. Young marine turtles, on emerging from the egg, crawl toward the moonlit sea (in response to reflected light). Newborn kittens and puppies, however, accomplish only a highly variable, nonvisual locomotion to the mother, and in specific activities have little more than crude sucking and righting responses. These mammals improve very slowly from birth in orientation and locomotion. At one week (before vision enters) the kitten returns slowly and inefficiently to the nest when set down nearby, mainly requiring tactual guidance. Although in the appearance of crawling in kittens and walking in human infants maturation is basic, limiting the rate of development somewhat as in lower vertebrates, in mammals the factors of experience have increasing weight.

Man's adult behaviour pattern appears later than that of any other animal and is the least specifically influenced by maturation. When a chimpanzee and a human infant were raised from birth in the same household, with similar treatment, the advantages of more rapid maturation were at first all in the chimpanzee's favour. At five months it exceeded the average one-year performance level of human infants in climbing, manipulating objects, and responding to companions. Although the chimpanzee's motor superiority continued, soon the human infant excelled in other respects. At one year, in acquiring word sounds, object meanings, and social meanings, the human infant far surpassed the chimpanzee. Man's psychological superiority over other animals rests on his greater potential for profiting from experience and not simply on his longer infancy and childhood.

2. Genetics of Behaviour.—Although genetic factors underlie all animal activities, heredity seems to influence behaviour more directly in the lower mammals than in the higher. Sexual patterns, for example, are less stereotyped in chimpanzees than in rats, as a result of evolutionary advances in the primate cortex which admit new relationships between structure and behaviour and make experience and learning more influential.

Correlational study of genetic factors and behaviour, in psychogenetics, offers techniques for comparison. For example, the trait of wildness appears to be dominant in the offspring when the gray Norway rat is crossed with the docile albino rat, and the behaviour of future generations as well as that of backcrosses of the hybrids indicates the opposed influence of different gene combinations (*see GENETICS*). With this knowledge the organic basis of such behavioural differences can be studied in different strains. The increasing difficulty, as maturity approaches, of

taming the young of genetically wild strains of rats, much greater than in domesticated strains, indicates that glandular secretions contribute to strain differences of this type. Supporting evidence is found in the fact that the adrenal glands of wild strains are larger than those of domesticated strains.

3. Influence of Experience.—Traditionally, species-typical activities appearing soon after birth (in isolated animals) have been considered inborn. But experience is not excluded thereby, as conditioned-response learning is demonstrated prior to hatching in certain birds and before birth in certain mammals, including man. Furthermore, under equivalent developmental conditions, experience may influence different individuals similarly and its role therefore may be overlooked. For example, Kuo found that the appearance of mouse-hunting behaviour in kittens depends upon a situation in which organic equipment is utilized. The kitten's first pounce is not hunting, but darting toward a moving object. This response resembles the forward lunge of certain lower vertebrates, except that in the kitten the new stimuli that enter and the patterns that eventuate are largely matters of experience. In the typical feline environment, pouncing soon leads to tasting blood, since the kitten inherits sharp claws capable of piercing the mouse's skin; tasting blood stimulates biting, and with experience the kitten becomes a mouser. Kuo obtained different results by varying developmental conditions. By always shocking kittens with mice present, he displaced pouncing with a fear reaction; by raising kittens with mice, pouncing was inhibited and social companionship developed. Thus, although certain species-typical equipment favours pouncing, drawing blood, and other events essential for mousing, mouse killing as a pattern requires certain interactions of organism and developmental field most likely to occur in the normal species environment.

4. Drive and Motivation.—Certain classes of behaviour once called instincts are related by modern psychology to drives. Drive is a term for physiological processes energizing individual behaviour. Examples are the thirst, sex, and hunger drives. Each of these patterns has its basis in physiological processes; for example, the sex drive emanates from complex conditions centring around glandular secretions, the hunger drive from both gastric processes and changes in blood chemistry. The influencing of changes in general behaviour by internal drive fluctuations has been established experimentally for many different animals. A classical example is G. H. Wang's demonstration of relationship between the ovarian (egg-maturation) cycle and periodic fluctuations of general activity in the female rat. Organic examinations showed that oestrous or heat periods recurred at four- to five-day intervals, and at corresponding times striking increases occurred in the daily amount of activity. Wang concluded that the activity rhythm depended on glandular changes incident to oestrus, as it disappeared in mature females after spaying and during pregnancy and was absent in immature females.

Some broad differences exist in the responses of different types of animals to drives. On maturing sexually, invertebrates and lower vertebrates tend to behave in more stereotyped ways than do higher vertebrates. A female solitary wasp of certain species, fertilized and with mature eggs, stirs about and excitedly stings a spider or other characteristic prey when it is encountered; an egg-laden jewel fish is particularly attracted by objects having certain general properties of movement, coloration and size. The effective stimuli are species typical. In contrast, the incentives or stimuli governing the drive-impelled responses of mammals, increasingly broadened and individually more variable than in lower vertebrates, seem related to superior aptitudes for learning through experience.

A related difference exists between lower and higher mammals in the ability to satisfy or change a drive tension through conditions related only indirectly to the original incentive. Thus a pat on the head stimulates a properly trained dog to intensive efforts but affects a rat much less. Chimpanzees can learn to work for poker chips which are then inserted into a food-delivery slot, whereby an inedible object acquires a measure of drive satisfaction for the animal. A comparable mammalian superiority in motivated behaviour is seen in the individual's ability to initiate

the secondary stimulus, as when a dog "ready for a walk" brings out his leash. Such behaviour has not been established reliably in reptiles or other lower vertebrates. (See also *Instinct; Motivation; Psychology, Physiological.*)

5. Sensitivity and Perception.—Von Uexküll and others have undertaken to describe the world of lower animals in terms of what is known about sensitivity. Thus one might speculate that for the honeybee in flight a flower patch is a flickering mosaic of colour with a glimmer of ultraviolet here and there; for the bird skimming low the patch has a distinct colour geometry without ultraviolet effects; for the house cat the scene has a washed out, colourless appearance. Such descriptions, from subjective inferences, are in the class of rudimentary speculation.

Only the first step toward understanding an animal's effective environment is accomplished by exploring its sensitivity. The chief problems are: what types of physical effects the animal is equipped to sense; what upper and lower limits (thresholds) hold for the various aspects (*e.g.*, intensity) in vision and other modalities; and what the acuity is in each field. In the sensory properties of animals, striking differences are found. Among the insects, the housefly, honeybee, and others, although blind to the long wavelengths of light seen by man as red, are visually sensitive to very short rays (the ultraviolet band) not seen by most vertebrates including man. Carnivores such as dogs, cats, and rats seem insensitive to wavelength differences in light which man sees as colours; whereas bees, many fish, and most diurnal birds and primates have a distinct wavelength sensitivity. Although these animals may not see hues as does man, they have colour vision, since under experimental conditions they can discriminate between wavelengths and between wavelengths and grays of corresponding brightness.

Important differences also are found in the ranges of corresponding types of sensitivity. Most fish can discriminate among intensities and pitches of sound; many crickets and other insects possess receptors known as chordotonal organs, sensitive to high frequencies of sound; many lower animals react to auditory frequencies above the human limits. The hunter's dog responds to the tone of a whistle near 30,000 cycles per second, soundless to the hunter, whose upper threshold lies below 18,000 cycles.

Striking sensory adaptations, important for orientation, are common. In bats, insect-feeding species and certain others have remarkable aptitudes for flying in the dark, long attributed to tactual sensitivity but found to depend on a keen perception of the bat's own ultrasonic utterances reflected from objects. When D. R. Griffin released bats in a dark room they flew skillfully among wires strung close together, but when hearing was eliminated by plugging the ears, or when the sounds were stopped by fastening shut the mouth, the skill disappeared. Highly delicate auditory reactivity of this type, known as echolocation, has been demonstrated in animals as different as certain shrews and some of the large aquatic mammals (*e.g.*, dolphins). Although echolocation has been found only in mammals, many birds and insects react keenly to high-frequency sounds produced by mates or by other animals (*e.g.*, certain moths move evasively in response to ultrasonic emissions of predatory bats). The work of K. von Frisch suggests that honeybees and other arthropods can orient with reference to the plane of polarization of light, a visual capacity still undemonstrated for any vertebrate animal. In most birds, taste is acute but smell is poor; in honeybees and many other insects, olfaction through antennal reception appears exquisitely acute but taste seems poorer than in man.

An animal's sensory equipment fundamentally influences its way of life. Bats and oilbirds can live in dark caves because of their delicate ultrasonic auditory sensitivity; mammals with keen olfaction can track prey by scent and tend to become night foragers, particularly (as in the cats) when dark adaptation processes favour dim-light vision. In contrast, animals with superior bright-light vision and inferior smell, as the diurnal monkeys, settle into a routine of daytime activity and nighttime sleep. Interesting relationships are often found between the fields of sensitivity and differences in habitat. There are species such as cave fishes living in complete darkness that have poor vision or are blind, with

tactual and chemical sensitivity highly developed. Comparable inverse relationships between vision and olfaction prevail in many insects. Most diurnal birds have excellent vision but are poor in olfaction. Sensory equipment basically defines the limits and the nature of an animal's world.

6. Sensing v. Perceiving.—Sensory data, although indispensable for behaviour, are not the best indicators of an animal's psychological standing. Many birds, for example, seem similar to man and are far superior to most lower mammals in visual acuity. Yet, in the critical matter of using sensitivity to master object meanings and their relationships, in which sensory factors are secondary, birds are inferior to man.

An animal's endowment for perception, definable as sensing in terms of meanings, is best judged according to how it deals with objects under varying conditions. The relatively stereotyped responses governing food-getting activities in cold-blooded vertebrates seem best interpreted in terms of relatively direct stimulus-response relationships (see ANIMAL BEHAVIOUR). For these vertebrates, object-organism relationships evidently depend mainly on specific characteristics, such as intensity and rate of movement; and not object meanings, and feeding depends essentially on what stimuli are adequate in their physical properties to elicit a reflex-like combination of forward lunge and mouth opening. These animals seem to behave far more in terms of seeing than of perceiving.

Basic in perceptual development may be early experiences, with low-intensity stimulation promoting soothing effects and approach, high-intensity stimulation disturbing effects and withdrawal (T. C. Schneirla). Early object attachments known as imprinting, demonstrated by Heinroth and by Lorenz in birds and later found in mammals, may be established on such a basis. Withdrawal fixations also may arise through stimulus-intensity effects in the early stages of life.

Vertebrate perception from the earliest stages may be influenced by such factors as sensory, neural, and motor thresholds effecting primary approaches or withdrawals. The so-called visual cliff phenomenon may account for apparent fear of heights in the young of many vertebrates. In experiments by R. D. Walk and E. Gibson, young chicks and weanling rats turned toward the seemingly shallow side of a partition on which a checkered pattern was located below glass, but away from the apparently deep side on which the same pattern was located 50 cm. or more below the glass. Chicks one to four days old and one-month-old kittens turned to the shallow side most of the time, but backed up and seemed disturbed when placed on the glass over the deep side. These responses appear in dark-raised animals, suggesting that the underlying factors are the differential effects of visual motion-parallax. That is, the near surface is seen as unchanged, hence is attractive or neutral; but the deep side is seen as in greater visual flux, and hence is disturbing.

7. Simplest Perceptual Relationships.—The organic basis of potentials for response to sensory change and for perceiving is evidenced in the lowest vertebrates. Minnows trained by P. Schiller to snap at the movement of a small bar of light presented with food then reacted to the light when it was presented twice within $\frac{1}{16}$ sec. in closely adjacent positions. The fish evidently perceived a movement, somewhat as would a human subject under comparable conditions. Experiencing apparent movement thus may be present throughout the vertebrate series. Many psychologists, and especially Gestaltists, consider this class of phenomenon an index of ability for distinguishing relationships, basic to perception.

It is probable that such abilities are essential to a meaningful sensing of objects. G. Révész presented chickens with successive pairs of circles, triangles, and arcs differing in size, the smaller one of each pair bearing food, thereby training the bird to peck only at the smaller figure in grain-free test pairs. Then two identical arcs were presented, one directly above the other, both with grain. The trained chickens pecked mainly at the upper figure, apparently seeing it as smaller than the lower arc, thus evidencing an illusion similar to that reported by people under comparable conditions. Correspondingly, chickens trained by

Köhler to peck at the brighter member of a training pair pecked mainly at the brighter card in new test pairs of different brightnesses. Similar results were obtained in equivalent tests of a chimpanzee and a human child.

Thus widely different vertebrates have a potential for reacting to successive visual situations as unities in which the members are bound together reciprocally. An organization of this type may be termed a relationship, although in the simplest cases the unity seems due to processes on a primitive level rather than to qualitatively superior intelligence.

8. Contrasts in Perceptual Ability.—Social insects normally accept members of their own colony but attack nestmates bearing the odour of another colony. That the perceptual capacities of lower vertebrates are comparably low is indicated in tests with species mates. Male Siamese fighting fish, for example, respond similarly to females and to artificial objects such as clay plugs, unless size is too great or movement too rapid, whereupon the artifact is attacked as are other males. Hence the male's responses to species mates evidently depend on physical characteristics but not meanings such as "mate" or "enemy." In pigeons, kittiwakes, and numerous other birds, a parent which feeds young regularly on the nest will neglect them when they are off the nest even if close by. Evidently the young have a very simple meaning for the mother bird, rigidly dependent on the nest locus (at least in the early stages of incubation) and much below the level of maternal perception in monkeys, in which mothers feed and protect their young under a variety of conditions.

Sensory Discrimination.—Critical for evaluating perceptual levels is the extent to which experience brings more versatile adjustments to objects under changing conditions. The first step is sensory discrimination, a learning to distinguish sensory differences and respond appropriately. As far as sensitivity permits, stimulative discriminations in every sensory field can be learned with appropriate responses by insects and other higher invertebrates, and by vertebrates from fish to man. The learning is relatively simple for a mammal, which characteristically requires fewer trials than lower vertebrates; the critical matter is whether the animal is sensitive and reactive to stimulative differences under the conditions. Thus dogs discriminate tones more readily than do rats because of better reception as well as superior sound localization and learning capacities. A hunting dog must first discriminate among types of animal scents (e.g., raccoons and rabbits), then he must learn to set himself for the one aspect of scent emphasized by his master.

Complex Discriminations.—The next degree is mastering complex compound stimuli, forming schemata in which successful response under experimental conditions depends on two or more characteristics of the positive pattern (e.g., brightness and size), two or more characteristics of the negative pattern, or on relationships between the positive and negative patterns. Correspondingly, the tracking dog at this stage distinguishes the correct scent from similar false scents depending on different combinations of characteristics.

Conditional Discrimination.—A qualitative advancement is that of conditional discrimination, which demands intelligence well beyond that required for simple discriminations and schemata. This step is not indicated for reptiles and birds, and may exceed the capacities of rodents. Problems requiring conditional discrimination arise when similar schemata are encountered in many situations with important differences in their relevance. For example, not all pet dogs can learn that unless the master also wears his hat he does not necessarily intend to go walking when he holds the leash. When an animal can give the critical response to the essentials of related schemata without mistakes due to conflicting details, he has mastered a set of contingent relationships termed an abstraction. For example, white rats after long training can jump to a triangle, however it stands, rather than to a circle; whereas chickens, having learned to differentiate these two figures in set positions, are lost if the triangle is tilted.

For success in conditional discrimination, aspects such as complexity in the combination of critical details from experience to experience are crucial. Discerning patterns in varying circum-

stances, in which confusing differences may obscure key details, is an accomplishment in the discrimination of relationships excluded to all but higher mammals. In contrast with the rat, whose limits for abstraction are soon reached, chimpanzees progress well in matching-from-sample tests, as N. Ladygina-Kohts found, and can single out a schema such as a triangle even when it is presented with others matching it in details such as colour and size. Monkeys, although less apt pupils than chimpanzees, can advance, as H. Harlow has shown, to very complex discriminations.

Very different attitudes have been taken in animal psychology toward the subject of perception. Some would use this term for any reaction to sensory effects, others would reserve it (as above) for grasping meaningful patterns through sensitivity. The former practice seems to have its basis in implicit analogies between any animal sensitivity and human consciousness of environment. On this view, the simplest sensory processes indicate perception. Such analogies, however, are vague. Modern experimenters prefer objective methods in which judgments of perceptual abilities depend on data from systematic object-discrimination tests under controlled conditions. The critical matter is not sensitivity alone but how the animal organizes sensory data in adapting to new conditions. For this, resources for learning are critical.

B. LEARNING ABILITY

The rich endowment of lower animals in species-typical adaptations related to structural specializations is well balanced in mammals by superior capacities for modifying behaviour. Writers such as E. Hering believe, however, that all organisms have memory, in that the action of a stimulus on protoplasm always leaves traces which influence further responses. In this very general sense, the term learning would be extended to the simplest types of behaviour changes through stimulation, as in plants and protozoans. An alternative view is that such changes should be classed as equivalent to the general kinds of trace effect termed hysteresis (*q.v.*) in physical systems rather than to learning as in higher organisms. For comparative psychology, the primary fact is not just the production of some trace effect through stimulation but what class of trace is involved, and what its relevance to the organization of behaviour may be.

1. Varieties of Learning.—Adaptation and Fatigue Phenomena.—The simplest types of trace phenomena are based on processes akin to sensory adaptation or muscular fatigue. A dog or a man in dim light undergoes chemical changes in the retinas to increase sensitivity in the dark. A worm, after circling counter-clockwise inside a dish, is likely to turn left when transferred into a T maze; a dog after running all day scratches himself weakly because chemical products have temporarily induced muscular fatigue. Similar instances based on changes in receptors or muscles are common throughout the animal series. They are not classed with learning because they centre on peripheral changes and not directly on central-nervous-system traces altering individual behaviour in persistent ways.

Sensory Integration; Habituation.—Certain classes of experiences may arouse neural trace effects influencing behaviour without altering it specifically. For example, in a phenomenon in mammals termed sensory preadaptation, after different stimuli such as a light and a buzzer are experienced together repeatedly without any specific action being involved, a response then conditioned to one of these stimuli also is elicited by the other without further training. In a similar phenomenon, generally termed habituation, commonly experienced disturbing stimuli lose their initial effect, and may even facilitate ongoing behaviour. Thus snails in an aquarium, bumped and otherwise disturbed for weeks by fish, then carry out their activities without the initial stoppages; a clerk becomes able to work in a noisy office. In such cases, through common experiences, neural traces are set up which influence behaviour in general ways.

Conditioned Responses.—In conditioned-response learning, the gain is a new stimulus-response connection, the nature of which depends on what specific stimuli are experienced together. To take an example from the lowest animal in which learning has been demonstrated, the marine annelid *Nereis* does not extend from its

tube in response to light or dark, but does so in response to meal juice. After the juice and either light or dark have been combined many times, the response is given to the latter alone. Conditioning, therefore, depends on what stimuli are combined under appropriate conditions. With each repetition, an unconditioned stimulus (B) which arouses the critical response (B_R) at the outset is experienced by the animal together with a conditioned stimulus (A) which initially does not arouse this response. Through experiencing the combination, the animal forms both an A-B integration and neural traces permitting A to control the critical response B_R . In the pioneering experiment of I. Pavlov with dogs, A was a bell sound; B, meat powder in the mouth, was a stimulus arousing B_R , a reflex salivation. Through repeated combinations of bell and meat powder, at length A- B_R was accomplished and the bell controlled salivation.

In vertebrates, and in higher invertebrates (*e.g.*, annelids), probably most reflexes and other local reactions may be conditioned if stimuli are appropriately paired. Although at first young dogs scratch only in response to local skin irritation (*e.g.*, flea bites), appropriately pairing this unconditioned stimulus with the smell of flea powder, hearing "Scratch!" or seeing his collar normally conditions the dog to form the corresponding A- B_R pattern. The potentialities of the conditioning principle for practical animal training depend mainly on ingenuity and patience, as is illustrated by a popular Soviet film of the 1950s portraying an enterprise in which dogs run trains, rabbits behave excitedly on missing them, cats punch tickets, and theatrical efforts are also represented convincingly, although evidently without understanding, by the actors.

In the mammals, particularly, aspects of the situation other than the focal stimuli can control behaviour through conditioning, thus serving as secondary conditioned stimuli. In Pavlov's work, stimuli incidentally seen and heard in the test room (*e.g.*, hearing experimenter's movements) at length elicited the critical response in the absence of the experimental stimuli. This enlargement of the habit was indicated also by a reduced responsiveness when the animal was tested in another room or without his harness. In such ways, in laboratory experiments or with pets at home, stimuli considered incidental or even overlooked come to control a habit, as in the Clever Hans case.

Conditioning is not the same in all animals capable of it but varies considerably in its internal pattern and relations to other behaviour. For this fact, differences in neural resources are critical. In invertebrates capable of it, and in lower vertebrates, conditioning is largely restricted to combining simple stimuli with reflex or stereotyped responses, and naïve responses to potent stimuli are reversed only with difficulty if at all. Examples are the difficulty of conditioning an inhibition of the snail's foot retraction to intense contact or the lizard's snapping at figures of complex but not smooth outlines. Mammals can form systems of conditioned responses in which a wider range of responses may be controlled by the same stimuli, the responses themselves varying more than in lower animals. The traditional milkman's horse, starting and stopping skilfully according to combinations of foot-step-and-bottle sounds, is an everyday example. The significance of such learning is illustrated by the great variety and flexibility of combinations possible through systematic training in almost any mammal, compared with the limitations of turtles, toads, and fish, increasing in that order.

From the lowest to the highest mammals the ability expands to modify conditioned responses according to prevailing conditions. It is difficult to condition a fish to move one fin alone to a light combined with shock, but with a dog, in time a light paired with shock to one leg controls not only the flexion of that leg, without the shock, but other changes also. Reduced forms of the conditioned stimulus and subtle secondary stimulus effects enter, and the response is curtailed and modified until at length the paw alone moves just enough to avoid the shock. Cases of learning in this class, in which both stimulus and response undergo precise modifications according to motivation and the consequences of action (*e.g.*, obtaining food or evading shock), evidently represent the merging of the conditioning type with the selective type of

learning (see below). The inferiority of lower vertebrates to mammals in such learning doubtless corresponds to differences in neural equipment. Thus, although normal dogs can be conditioned to withdraw a specific paw skilfully on signal, dogs deprived surgically of cerebral cortex advance little beyond the stage of general excitement and variable responses to the conditioned stimulus. The limitations of dogs without cortex remind the experimenter somewhat of lower vertebrates with their inferior neural equipment. (See also **CONDITIONING**.)

Operant Learning.—Variations of conditioning are possible depending on the animal and technique used. A method known as operant learning approximates conditioning by routinizing stimuli and other conditions, but differs from it in that initiating the response depends specifically on the animal. In the classical experiment of B. F. Skinner, a rat learns to approach and press a bar for a food reward. If the reward is given only in the presence of a signal, say a light, the rat will tend to press the bar during presentation of the light and not in the dark. If his hunger is reduced, he stops pressing, and so on. This method is very useful for research on the properties of sensory discrimination, reaction, and drive; however, it may not be suited to the comparative study of learning. In the operant method, the experimenter plans the situation for the animal so that the successful response is sure to occur. Despite the specific utilities of this method, the fact remains that by selecting what action is to be correct, and by maneuvering the animal's behaviour so that this action occurs, the experimenter substitutes his own role for unexamined selective processes otherwise dependent upon the animal. By this method, therefore, similarities are obtained for pigeons, rats, and men which may be misleading. (See **LEARNING**.)

Trial-and-Error or Selective Learning.—This complex form of learning, not clear below arthropods, reaches its peak in the mammals. It is illustrated by the behaviour of a hungry dog outside a food box that can be opened only by pulling a cord. The first responses of dogs to such problems are highly varied, and include nearly all activities possible under the conditions; from pawing and sniffing at the box and at the floor nearby to running about at intervals and also, finally, sitting and howling. At length the dog, in the course of biting and pawing at objects, happens to pull the cord and enters the door to food. The first trial, particularly, is likely to be very long, but, as E. L. Thorndike found in his pioneering work with cats, random activities decrease and the cord is pulled more and more promptly in further trials. From these characteristics, such learning is called trial and error. Because the animal improves by working more frequently in the correct locus and adapts more efficiently through organizing appropriate responses from initial variable behaviour, the process may be termed selective learning. When D. K. Adams prehabituated animals to the general situation, thereby reducing initial disturbance and emotional excitement, random behaviour decreased and the correct solution was more promptly and efficiently acquired than in naive animals.

Many kinds of problem situations have been used in studying selective learning, including types in which avoiding shock or getting food depends on pressing a pedal or pulling a string, combinations of these, and other devices. Higher mammals such as the chimpanzee can solve problems involving latch combinations which are difficult for the monkey and insoluble for rats and lower mammals, not merely because the chimpanzee excels in manipulative ability but because of his superior capacity for organization in learning. Birds, in contrast to mammals, are limited to easier problems, which they learn more slowly. Sparrows are slow, pigeons much slower, in

FIG. 3.—SIX-BLIND MAZE PROBLEM USED FOR TESTING BOTH ANTS AND RATS. SOLID LINE INDICATES TOTAL-ERROR SCORES OF EIGHT ANTS, BROKEN LINE, THE TOTAL-ERROR SCORES OF EIGHT RATS

learning to press a string admitting them to a food box, then do not relate the string response to the act of entering the door. The bird's inferior organization of the habit is shown by the fact that, with the habit learned, if the string is moved he tends to work in the habitual place instead of directing his efforts at the shifted string, as most dogs would. The inferiority of lower vertebrates to mammals in problem solving, as W. Fischel has shown, lies especially in their shortcomings for interrelating the critical act (e.g., string pulling), the object acted upon (e.g., the string), and the goal (food).

A method much employed in studying selective learning involves the maze, in which establishing a correct route despite blind alleys makes possible investigating both the elimination of errors and the organization of a complex orientation habit. Animals from earthworm to man have been tested, and striking differences are found. To learn a T maze with only one blind alley the crab *Cambarus* needed more than 60 trials, chimpanzees only a few. In about half the trials needed by the crab for its simple learning, *Formica* ants master mazes containing six blind alleys. Rats, on the other hand, given this pattern used for the ant in an appropriate scale, need only 12 runs or less.

As Schneirla has found, submammalian animals require more trials to learn comparable problems, commit far more errors than mammals, and accomplish an inferior habit in a different and more limited way. The ant, to learn the six-blind maze mentioned, first became habituated, next mastered local difficulties, finally a general organization of the habit, all very gradually. The rat, in contrast, exhibited no distinct stages but mastered local difficulties and organized the general route simultaneously. The superiority of the rat's habit is shown by its facile modification when maze changes shift the correct route through a former blind alley. The rat reverses maze habits readily when required to start at the former exit, whereas for the ant this is a very difficult

problem. The ability to reorganize behaviour in new situations is a particular mark of the mammal's superior capacity for selective learning.

Tests requiring modifications in learned habits reveal even more clearly than do studies of initial learning how strikingly different the capacities of ants and rats are for organizing solutions of comparable tasks. To compare fish and rat in this respect, M. E. Bitterman and J. Wodinsky used a technique requiring successive reversals to the stimuli of a discrimination habit. Although in these experiments the rats improved steadily from day to day in shifting between two similar alternative habits, the fish usually failed to improve except within given days, and in successive reversals their habits seemed to interfere with each other.

When learning is reviewed comparatively (as in the foregoing discussion) the possibility arises that the chief difference between invertebrates and lower vertebrates, on the one hand, and mammals on the other may not so much involve the formation of neural traces, emphasized by S-R learning theory, as in capacities for organizing traces, emphasized by other theories. Thus, using food or shock in training techniques may be important in infra-mammalian forms mainly for the rate of forming the neural traces themselves, although in mammals its influence on the course and organization of selective learning can be much greater.

For good results in training mammals, although conditioned-response procedures may be held basic, the use of punishment or reward to control what is learned must be tempered by a broader conception of the role of incentives and motivation than would be necessary for lower animals. Accordingly, for mammals, punishment is advisedly used only in mild forms (as intense stimuli emphasize avoidance reactions to trainer and situation) and reward, similarly, to encourage desirable responses and their efficient organization.

2. Experience and Abilities in Learning.—Mammals surpass invertebrates and lower vertebrates not only in learning new problems but also in reorganizing habits adaptively. Adapting to this comparison the neurophysiological theory of D. O. Hebb for the ontogenesis of perception, one would say that rodents and higher mammals, with further related experiences, advance much more readily than lower forms from trace effects to linkages to complex neural patterns. Mammalian learning is typically more efficient in familiar situations not only because the animal is less excited and behaves less erratically than under strange conditions but also because mammals can extend habits progressively to better effect than can lower animals.

Virtually any type of problem is mastered more readily by mammals, not only because of their superior organic equipment for original learning but because experience is brought more effectively to bear on further problems. Harlow investigated these matters at length with monkeys given long series of discrimination tests with problems of increasingly difficult natures. Results showed that monkeys master more complex discrimination problems of the same general type with progressive facility. Harlow applied the term "learning sets" to the successive stages of the monkey's progress in learning to learn. He was inclined to emphasize the similarity of learning at successive stages and to doubt that qualitatively new processes enter at the advanced stages. But, as N. R. F. Maier and Schneirla suggested, the discrimination method may not be adequate to reveal qualitative differences in learning. This problem seems to require other methods more appropriate for the investigation of similarities and differences in learning and intelligence at different animal levels.

C. INTELLIGENT BEHAVIOUR

1. Criteria.—Intelligence (*q.v.*) is definable as the ability to utilize experience in adapting to new situations. Intelligence is not efficiency in adaptive behaviour, a quality shared by all surviving animals. Furthermore, although intelligence depends to some extent on the organism's aptitude for conditioning, and more so on its aptitudes for selective learning, the crucial matter is how readily the gains of past experience are adapted to new problems.

It is difficult to diagnose any solution correctly without adequate knowledge of the animal's background. Morgan described a case in which, after he had observed a dog in repeated erratic attempts to pull a crooked stick through a paling fence, the animal finally yanked the stick through when the crooked part accidentally broke off. A passer-by, who saw only the last and successful part of the series, remarked, "Clever dog that, sir, he knows where the hitch do lie." Whether success results through accident, a gradual process of selective learning, or an efficient reorganization of experiences appropriate to the problem may depend on (1) species abilities, (2) the abilities and experience of the individual, and (3) the conditions under which the difficulty is encountered.

2. Insight.—Commonly accepted as an index of intelligent behaviour are short-cut solutions known as insight, in which the animal appears suddenly to see the point. Calling such solutions insightful does not of course explain them but may only analogize success with a hypothetical process of seeing into something. The mere rate of accomplishment does not indicate insightful solution, for insects in certain problems occasionally achieve rapid but noninsightful improvements. Insight involves a kind of organizing ability not demonstrated in insects or lower vertebrates, superior to both conditioning and selective learning for overcoming new difficulties.

Pioneer studies by M. Haggerty and others shortly after 1900 revealed that problem solutions by monkeys are often better than would be expected through trial-and-error processes alone. For example, a monkey, after having watched another, in four successive trials, climb the side of a cage and reach into a chute to obtain fruit, when given the problem himself soon solved it by working directly around the chute until he reached the fruit. Later, in the research of Köhler and Yerkes particularly, similar abilities were demonstrated for chimpanzees, superior to those of monkeys.

In these experiments, chimpanzees were presented with problems such as food overhead or behind a fence, unobtainable by direct responses such as reaching or jumping but obtainable only by indirect procedures. Although there were failures and some animals never did well, some of the chimpanzees reached distant food by means such as stacking boxes or raking it in with a stick. One of Köhler's chimpanzees, which had previously used only single sticks as rakes, was shown food beyond reach, requiring a stick longer than any available. First there were actions such as merely reaching out with the arm, or using one bamboo piece alone or to push out another, for getting at the incentive. Even though inappropriately, the animal in such behaviour was using foreign objects as a means to an end—in other words, as crude tools. After an hour, the goal was unattained and the animal sat facing away from the food, idly handling two bamboo sticks. Then a change appeared, as follows:

Sultan . . . picks up the two sticks, sits down again on the box, and plays carelessly with them. While doing this, it happens that he finds himself holding one rod in either hand in such a way that they lie in a straight line; he pushes the thinner one a little way into the opening of the thicker, jumps up and is already on the run toward the railings, to which he has up to now half turned his back, and begins to draw a banana towards him with the double stick. (W. Köhler, *The Mentality of Apes*, Eng. trans., 1925, Harcourt Brace.)

That the sticks were perceived as a useful tool and not combined by accident was indicated by the fact that when the pieces happened to separate, the animal straightway recombined them in a manner seemingly impossible without some understanding of their function together.

3. Relative Aptitude for Indirect Solution.—Solutions of such types resemble the pattern recognizable in mammals as perception of relations. Much evidence indicates that lower mammals are inferior to primates in this respect. Cats and dogs can learn to manipulate levers, but neither can assemble a tool or use it as chimpanzees can in solving problems.

Köhler emphasized the superiority of primates over lower vertebrates in correcting their initial direct responses to the incentive, when necessary, with indirect ones. A hen separated

from food by a wire fence persists in zigzag running against the fence, opposite the food, whereas dogs in time abandon direct responses for a detour to the food, and monkeys do so sooner than dogs. Fischel demonstrated that although dogs can respond to one of two incentives with the direct or indirect action that is appropriate, thus solving a task failed by turtles and by birds, they master the critical relationships less effectively than primates do. Chimpanzees clearly surpass monkeys at solving the type of problem requiring the subject to push food away from him around a barrier before raking it in, indicating a superior mastery of the relationship of the subject's position, the barrier, and the goal.

4. Reasoning as Reorganized Learning.—Indirect or insightful solutions are frequently differentiated from patterns acquired directly through selective learning in that the former type of solution often appears suddenly, after a period of apparently fruitless trial and error. Sudden improvements in progress toward or in attaining a new type of solution are notable in the problem-solving behaviour of higher primates such as chimpanzees, less prominent in monkeys, still less in dogs, cats, and rats in that order. This fact does not mean that insightful solutions occur independent of previous learning.

Insightful solutions have not been clearly demonstrated in any inframammalian animal, and various anecdotal claims for such processes, as in insects, seem attributable rather to uncontrolled possibilities for direct responses. What is unique about insightful solutions is that they are attained by reorganizing two or more patterns of response available from experience in similar situations, although previously independent of each other. Thus, perceptual adjustments such as jumping to food and handling a box may exist separately in the animal's repertory until he combines them in solving a new problem. In one of the experiments of Maier, who studied simpler forms of this type of solution in the rat, the subject was first habituated to the elevated pathway shown in fig. 4, passing between each two tables frequently, without receiving food. In the test, the rat was first given food on one of the tables, e.g., no. 3, then was transferred to no. 1, for example. On the basis of his specific habits, the rat in this case would have turned with equal readiness to tables no. 2 and no. 3; the results, however, showed that adult rats were able to return with better than 80% success to the one food table correct in the particular test. Achieving correct solutions when a direct recall of learned responses would have led to chance scores indicates a capacity for combining learned items which had been separate in previous experience.

Maier emphasized the qualitative similarity of such solutions to reasoning in man. As an example of a solution by reasoning, not demonstrated in mammals below primates, the joining of short sticks when a longer one is needed has been mentioned. As H. Birch found, however, chimpanzees cannot solve this stick-combination problem by reasoning unless they have previously handled sticks as in play and appropriate unitary perceptual adjustments are thereby made available. The feat then is to combine these elements insightfully in an intelligent adaptation to new difficulties.

5. Relative Independence of Stereotypy.—*Nonsoluble Tests.*—Mammals differ greatly in their freedom from stereotyped behaviour in problem situations, as G. V. Hamilton found. In his nonsoluble test, the subject was presented with four doors, one door unlatched on each trial, but never that unlatched on the preceding trial. This fact was discovered by the human subjects, but not by any lower animal. Next in complexity of response were monkeys, the other primate tested, which often tried all four doors successively and distributed their efforts without trying any

one door repeatedly on any one trial. Stereotypy of response, or repeating particular reactions frequently, occurred often in dogs and cats and very often in horses. Significantly, the tendency for stereotypy and persistent repetition of errors is marked in the maze learning of rats in which 20% or more of the cerebral cortex has been destroyed. Maier found partially decerebrate rats very inferior to normal subjects on reasoning problems, much as lower mammals are distinctly inferior to primates on such problems. Superior cortical endowment thus inhibits stereotypy in mammals so that new adaptations become possible.

Multiple-Choice Test.—The Hamilton situation was adapted by Yerkes in further studies of plastic behaviour in his multiple-choice test. Here the subject faced nine doors in an arc, with a sequence of five doors unlatched on each trial, but (to eliminate simple position habits) always a different set. Food was to be found behind just one door each time, and the problem was to discover how the correct door was systematically related to the others. Sample problems were: (1) always first at the right; (2) always second from the left; (3) always the middle door. The aim here was to compare the levels of intelligence in different animals. In the above problems (1), presumably the simplest, was solved both by the crow and the rat; they both failed (2). Problem (3) was solved by the monkey but not by the pig. Chimpanzees solved problems more difficult than (3), in which success may have depended on ability to abstract a significant pattern from among complex settings, or on what Yerkes called "ideational processes." To the claim that the multiple-choice method is valid for testing animal intelligence comparatively, critics object that the method affords no basis for clearly appraising such processes; also that it handicaps some animals unduly by admitting irrelevant features such as emotional reactions, which may have caused gorillas to fail problems solved by chimpanzees.

6. Representation as a Secondary Factor in Reasoning.—Attaining solutions by combining previously independent experiences, demonstrated in lower mammals including rodents, represents the reasoning process in simpler outline than in man. Animal psychologists have studied "mental processes" in lower mammals, in comparison with man, to find what other factors are contributive. One interesting method is that of delayed response, an outcome of earlier attempts to test capacities for "ideas." In the form developed by W. S. Hunter, this method involved first training the animal to go through the one of three doors marked by a light; then, in tests, the lamp over one of the doors was first lit briefly and after a given delay the animal had to respond without the light. In modifications of this test by others, the animal was first shown food under one of several cups or saw food buried, and after a delay had to locate it.

The general result of such experiments, although specific results differ according to procedure and situation, is that lower mammals require more preparatory training for success and in general rely more on specific bodily orientation during certain types of tests than primates do. In food-concealment tests, monkeys and chimpanzees can delay successfully over intervals of 24 hours or longer. The general interpretation is that success depends on an ability to represent the absent object or the appropriate adjustment to this object as a cue for recalling its location after the delay. Ability to delay the correct act over an interval is often interpreted as centring around an abbreviated form of the actual adjustment; lifting a box, for example, might be represented by a slight tensing of the arm muscles as in raising the box. In comparison with man's great advantage of symbolizing experiences verbally, lower mammals are handicapped by having to represent their adjustments in much less versatile ways.

A related ability indicated in lower primates and certain other mammals is the anticipation of particular absent objects. In one delayed-response experiment with monkeys, in which banana was used in some of the trials and lettuce (less preferred) in others, the subject became disturbed and refused a piece of lettuce surreptitiously substituted for the banana he had seen concealed before the delay. Evidently the animal then specifically anticipated banana, for lettuce was accepted readily in delayed trials preceded by the showing of lettuce.

ADAPTED FROM W. R. F. MAIER AND T. C. SCHNEIER, "PRINCIPLES OF ANIMAL PSYCHOLOGY," REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO.

FIG. 4.—MAIER THREE-WAY APPARATUS FOR TESTING REASONING IN THE RAT (see TEXT)

The ability to represent absent objects and situations may be considered a contributory factor in reasoning. This type of process is suggested by trials in which a chimpanzee, after having worked at suspended food for some time without success, suddenly rushes around the corner for a box previously seen there, then promptly uses this box in a solution. The ability to represent absent objects, although it aids solutions by reasoning, cannot alone account for such solutions, for merely representing an experience without change or recombination would constitute a direct recall rather than a new solution. In the primates, the newness of solutions achieved through reasoning is far more striking than in other mammals.

V. MAN COMPARED WITH THE LOWER ANIMALS

Although man is not the most highly evolved animal in all aspects of structure, he is psychologically the highest. His superiority is not absolute, however, for most of his advantages are also shown, though to lesser extents, by mammalian relatives.

1. Time, Reasoning, and Foresight.—Although reasoning seems to be carried on by mammals down to rodents, in the lower orders it is simpler and evidently plays a far smaller part in adaptive behaviour than it does in man.

Man's psychological advantages include foresight and time-binding, or reasoning with reference to problems in the more distant future or past. Time-binding, for lower primates, is largely restricted to the present and is much less extensive and meaningful for the past than it is for man, who thinks in the future as well as in the past and present. The apparent anticipations of lower animals can be conditioned within limits to coming phases of recurrent events, through internal or external stimuli characteristic of given times of day. In rodents, discrimination of short intervals of time in terms of action has been demonstrated; however, their apparent anticipations are held to shorter intervals and simpler processes than in primates. Even in apes, anticipation evidently endures far more briefly than in man, and largely involves more familiar occurrences. The ability to think far forward in time seems to require a wider reorganization of the traces of experience than is found in any lower animal.

Man is capable of systematic sequential reasoning, or planning, organizing into systems the traces of very different experiences with reference to future goals. Foresight in the chimpanzee is typified by his food expectancies, anticipative of specific episodes only a day or two off. If lower primates can reason to obtain goals or forestall hazards expected in the more distant future, these abilities remain undemonstrated.

Planning for future needs requires not only foresight but also reflective thought, or reasoning about one's own condition in relation to the past, present, or future. Differentiating and identifying the self in thinking, marked typically by the first significant use of personal pronouns (*e.g.*, *me*, *I*, *my*) at about two years of age, is a major event in human development. This symbolic accomplishment is far superior to reacting emotionally about one's own behaviour or appearance, as might a monkey observing himself in a mirror, or a growling dog preparing to fight.

Foresight involves taking note of one's own status or condition, in reference to that of other individuals, objects, and situations, to achieve appropriate measures. This type of self-reactive reasoning expresses man's superiority over the lower primates better perhaps than any other aspect of development. The comparison is weakened neither by subnormal human intelligence nor by the fact that any man at times uses his abilities poorly. The best human foresight infinitely surpasses the best in subhuman primates.

2. Verbal Language and Communication.—Although language and communication are often confused, the former constitutes a special case of the latter. In communication the behaviour (or related aspects; *e.g.*, odours) of one animal influences the behaviour of others. Thus, odours produced from an excited bee's scent glands mark the food place and attract other foragers; deer and other mammals, by rubbing parts of the body against projections, leave traces as territorial cues to other animals. The flashing of fireflies; the chirping of crickets; and the colour changes,

movements, and sounds of mating animals are by-products of excited behaviour frequently crucial to species adaptation. Such behaviour, although significant in communication, does not appear to involve symbolic processes equivalent to human language.

Honeybees, as reported by K. von Frisch, have been accepted by some as using language. Finder bees seem to communicate the location of food sources they have found by performing a kind of dance (*see* SOCIAL INSECTS: *Social Bees*). However, the dance seems to be a physiological by-product of feeding and flight; its effect on other bees is stereotyped and physiological and many authorities deny that it meets the criteria of language (*e.g.*, it seems to lack conceptual organization).

Communication approaches closer to language when social responses advance through conditioning, as in groups of birds or mammals when the excited cries of one individual throw others into flight. Another advance is made when a general activity is modified through experience into a special device used to influence the behaviour of others, as when barking and biting in a dog change into baring fangs and growling as means of intimidation. When merely beginning the act often causes flight, the abbreviated form is learned as a special social device. Instances of simple, discrete communicative processes of this sort are not uncommon in the everyday life of mammals, as in the "begging" of hungry dogs and the mewing of cats before closed doors. When used with even a limited anticipation of their social effects, such acts approach the stage of language.

Infrahuman primates seem not to develop systems of symbols in the class of language. Yerkes, however, from his extensive experience, indicated in the chimpanzee a variety of sounds and movements which influence other individuals, keeping them in touch with and informed about the presence and attitude of one another as well as about significant features of their environment. To be sure, these sounds and movements of lower primates more often appear as incidental features of the first animal's excitement (*e.g.*, the "hunger cry") than as intentional means of informing others of something. Although proof is lacking that chimpanzees use sounds symbolically, S. Crawford and H. Nissen demonstrated experimentally that these animals can use gestures as language symbols, as in tapping the shoulder of a lagging companion when food can be obtained only with his cooperation.

Man alone seems able to develop and use systematic codes of language symbols. Nonmimetic, conventional types of symbols, particularly, qualitatively distinct from the acts or objects they represent, account for the great efficiency of human language. In contrast, the communicative activities of lower mammals are essentially mimetic in that the sign or signal is a specific part of a series of experiences which represent the whole. Even the chimpanzee, which has a facility for vocal utterances and an intelligence that make it perhaps the best candidate for language next to man, falls short of achieving verbal language symbols. Attempts to teach chimpanzees true words attain only the stage of stereotyped responses given under set stimulus conditions. Parrots can learn to repeat frequently heard sound patterns, which, however, constitute skilled acts largely devoid of any meaningful association with the objects or situations eliciting them and are not manipulated with anticipation of the results; hence, not language.

3. Conceptualization and Intelligence.—The psychological deficiencies of chimpanzee as compared with man, and of monkey as compared with chimpanzee, relate significantly to the elaboration of brain cortex. In the mammalian series rat-dog-monkey-chimpanzee-man, there is not only a progressive increase in the proportion of cerebral cortex to body weight but also an increase in the number of cortical cells and the complexity of their interconnections. Such increases parallel improvements in potentials for complex functions centring around learning and its reorganization in perceptual, conceptual, and language processes. This is validated by findings such as K. Lashley's of a high positive correlation in rats between amount of intact cerebral cortex and performance in learning problems, and Maier's that losses exceeding 20% of cortex abruptly reduce to a minimum the scores of rats in reasoning tests. Limitation of symbolic behaviour by

the amount and pattern of cerebral cortex is emphasized for man by the deficiencies of imbeciles and by the degeneration of symbolic functions in step with progressive cortical loss as in tumours. In the final stages of such disorders, the patient may see once familiar objects without being able to name them or recall their meanings.

Mastery of verbal language symbols evidently requires a foundation in object meanings beyond the resources of subhuman intelligence. To be sure, a chimpanzee can be taught human activities such as using utensils, yet the circumstances of training and of use indicate a limited perceptual and conceptual command over the adjustments, and a performance more rigidly bound to specific sensory properties and motor routines than in man. The chimpanzee thus can learn to ride vehicles without forming the abstraction "ride" and using it verbally to initiate the act as does the human child through mastering the common properties of vehicles. Although human infants in their first symbols are bound to particular situations and concrete uses, later they progress steadily with verbal symbols whereas chimpanzees remain in the nonverbal stage.

4. Emotion.—In higher and lower animals alike, a relationship may hold between outer causes and the individual's initial excited, emotionalized responses. Although in the higher mammals these processes progressively involve perceptual states of variable stability and psychological complexity characterized as pleasant or unpleasant, they are grounded in visceral conditions. Primitively, strong stimuli elicit withdrawal and an interruptive visceral condition; weak stimuli, approach and a vegetative visceral condition. What may be called the strong emotions, characterized by interruptive visceral changes such as hampered digestion, quickened heartbeat, secretion of adrenin, and impulsive responses such as flight or fighting, are aroused by intense stimulation. W. Cannon identified equivalent interruptive physiological reactions of these types as accompaniments of strong emotional excitement in both lower mammals and man, "putting the organism on a war footing." Conversely, weak stimulation promotes vegetative changes such as facilitated digestion, and the related overt response is an approach toward the stimulus source, naïvely in mammals a general relaxation and reflex extension of limbs. The interruptive condition seems inherently episodic, the vegetative condition relatively continuous and potentially basic to social life. In mammals, however, with their capacities for psychological plasticity, which of these becomes dominant in personality and society seems increasingly dependent on the prevalent development conditions. Lower mammals and very young children readily tend to perceive objects and situations in terms of their general emotional associations, as conditioned-response learning prevails first. Under severe environmental conditions, with punishment and strong stimulation frequent, interruptive emotional tendencies may become dominant, as in the trembling, cringing, whining behaviour of a frequently punished dog when the whip, his master, or a stranger is encountered. In contrast, an emphasis on approach tendencies and selective learning in development brings intelligence to the fore and contributes to social rather than asocial behaviour.

In man, visceral processes play a far more indirect and delicate role in emotional reactions which are much more influenced by the perceptual significance of the situation than they are in lower mammals. Because man's emotional development is dominated by his perceptual and conceptual processes, according to circumstances, it is unsafe to infer experiences of fear in the human sense in the excited flight of insect or fish from a suddenly moved object or maternal love in the queen ant licking her first brood. That the difference depends particularly on the intimate involvement of cerebral function in man's emotional development is indicated by lapses in emotional specialization and social restraint with cortex-inhibiting agents such as alcohol or more lasting deficits when brain tumours or injuries reduce cortical function. Comparably, in cats and other lower mammals, when the cortex and brain stem are disconnected surgically there are marked increases in activities such as snarling, biting, panting, and other signs of interruptive visceral disturbances normally episodic and associated with high emotional excitement. Man's cortical equip-

ment admits an emotional specialization comparable with his intelligence, and involved with it in an intimacy well beyond the range of lower mammals in general.

The temperamental resemblance of lower primates to man appears much closer than their intellectual resemblance to him. Although well-domesticated dogs are frequently very sensitive to subtle differences in human behaviour, acting almost as members of the family, domesticated chimpanzees seem far more delicately and complexly attuned both to man and to chimpanzee companions. Hebb, by simulating the approach of a timid man and of a bold man in successive tests, obtained significant chimpanzee responses, with one animal friendly in the former situation but aggressive in the latter, two others interested but aggressive and unafraid in both. The first animal may have been hoodwinked by the act, the other two not, as the experimenter was known to them.

Experienced observers report patterns meriting terms such as confidence and discouragement, bluff, suspicion, and others, appearing under comparable conditions in the ape and the human child. These responses involve rough similarities in external signs of emotionality, including facial expressions and general tensional changes, reliably interpreted as indicating emotional attitudes. A common difference is that, in excited emotional responses, overt processes tend to emerge more readily in adult lower primates, with the whole body involved as in stamping and shrieking when rejecting something, and in this sense they are much more dominated emotionally than adult man.

5. Aesthetic Perceiving.—The potential for perceiving objects or situations in emotional terms such as distress or reassurance appears first in mammals. Although in lower vertebrates and some invertebrates stimuli such as body colours or characteristic sounds may be excitatory or calming, repellent or attractive, evidence suggests that specific effects such as intensity (controlling physiological changes), and not their perceptual significance, dominate such responses. Neither simple conditioned responses nor naïve responses to stimuli are truly aesthetic, in that emotional effects accompanying attraction or repulsion reach the level of appreciating object significance, object qualities, and emotional effects as related.

Simple aesthetic perceiving, so defined, is indicated in the subhuman primates. Köhler observed chimpanzees hanging material such as plants or fruit skins about their necks or shoulders, or applying clay or other substances to their bodies or to surrounding objects. Other behaviour was seen which Köhler considered rudimentary dancing, as when animals pranced around a circular path in single file or stood in pairs, one stamping the feet alternately as the other rotated with outstretched arms. Such actions are accepted as primitive types of aesthetic perceiving both because individuals evidently derive an emotional gratification from manipulating object qualities with reference to themselves and because these actions exert an emotional effect on others. D. Morris, from studies of finger painting by chimpanzees in the London Zoo, suggested that free-choice and project methods often reveal indications of aesthetic appreciation in selecting and combining colours, somewhat comparable to the tendencies of human infants. B. Rensch thought that the preferences of *Cebus* monkeys for certain combinations of colours and grays, and certain geometrical patterns, express processes resembling some of the simpler aesthetic tendencies in man.

The potentials of lower primates for aesthetic perceiving are slight in comparison with the potentialities of man, who alone seems able to create systematically visual patterns such as thematic paintings, auditory patterns such as symphonies, or dances worthy of choreography with the expectation of exciting appreciative emotional responses in himself and others. Not only are the chimpanzee patterns vague and lacking in subtlety, but their significance apparently involves only a momentary emotional appreciation, as abilities are lacking for the intellectual synthesis of emotional effects and patterning of material essential for a wider orientation in time. The human artist, with an appreciation of his own relationship to the theme and resources for planning his work to play upon the emotional susceptibili-

ties of others, can treasure and recreate aesthetic experiences. Through his foresight, experiences remote in time and space and with disparate meanings are continued creatively to enrich the environment for himself and others.

6. Personality and Abnormal Behaviour.—Normal behaviour is definable as the developmental pattern characteristic of the given animal group. The major animal forms have been compared here in terms of their normal or typical patterns. Although this is justified, it is also true that every species presents individual differences in all characteristics of behaviour. Individual differences in organic characteristics and in adaptive behaviour constitute an important fact in evolution. Generally such variations are predictable, in that correspondingly fewer individuals deviate from the species norm in more radical ways. Some ants or bees are superior and others inferior to most of their colony mates in orientation, foraging, and nest activities; chimpanzees differ widely in abilities from reaction time to reasoning.

Individual differences that are matters of degree in sensory acuity or in the efficiency of learning may be considered regular or ordinary. Radical psychological deviations from typical species behaviour are uncommon in the lower animals, although special departures may result from extraordinary conditions as in development. Pathological conditions affecting the nervous system can produce behavioural eccentricities. Thus the signs of rabies in dogs and other mammals are extreme emotional excitability with indiscriminate running and biting; brain tumours produce sleepiness, reduced sensitivity, irritability or depression, and other extraordinary signs according to their locus and extent. Man seems to be the animal most frequently plagued by psychological complications arising through disrupted organization of behaviour rather than primarily through nervous system lesions.

Under special stress, lower vertebrates may exhibit emotional disorders resembling those of man. Gun-shy dogs tend to be extremely fearful in specific situations, and perhaps generally, because of emotional conditioning. Disturbances resembling neuroses have been produced in mammals and also birds with Pavlovian conflict technique, in which an animal, trained, for example, to respond to a circle but to inhibit response to an ellipse, is then forced to respond to a figure intermediate between these two. As the animal cannot both respond and inhibit response simultaneously, a conflict condition results, with tension, excitement, and even violent movements, and usually great difficulty in repeating either habit (*see* NEUROSES, EXPERIMENTAL). Under marked frustration in problem situations, with strong hunger but with no response adequate to get food, chimpanzees and other mammals become emotionally disturbed, negativistic, and neurotic. Frequent experiences of this sort cause lower primates and human children alike to exhibit symptoms such as temper tantrums or chronic sulkiness with evasion of or dependence on others rather than attempts at direct solutions. By frustrating chimpanzees from infancy, with frequent stress and blocking of strong motivation (as many human parents treat their children), one may obtain abnormal symptoms resembling human neuroses.

One important reason that types of disorganization common in man are less prominent in his animal relatives centres around the infrahuman deficiencies for redirected motivation, perception, and reasoning, and the consequent lessening of morbid anxieties about unobtainable goals. When a chimpanzee is away from the scene of its frustrations, its limited abilities for symbolism hold down related emotional stress in other situations. The effects of frustration are thereby reduced for the animal and it is freer to recuperate than is a man, who can recreate and enlarge on the situation with its tensions.

Lower animals are not so dominated as man by remote goals or dangers or by attitudes of personal prestige; they are freer to leave the frustrating situation outright. Even so, symptoms frequently arise with some resemblance to human reactions in frustrating situations, as in caged mammals persistently circling their enclosures. Such stereotyped habits tend to reduce tensions from conflicts between escape motivation and the necessity to remain. Such behaviour is adaptive in that it seems to help the animal survive frustration; similarly, in man, delusions and other

symptoms may forestall more serious disorganization.

7. Contrasting Social Patterns.—Aggregations are fairly common among all animals. Cells of sponges and other colonial organisms are unified organically, members of general associations remain together temporarily through common responses to the same extraneous stimuli. Social groups as in insects, birds, and men are unified and organized on the basis of interdependence.

Natural selection has placed a premium on mechanisms making for interattraction and grouping of species members. As W. C. Allee demonstrated, even the biochemical products of death facilitate survival of others in various invertebrate associations. In insects and mammals, secretions and other processes have evolved which attract members of the species to one another, facilitating unity in local groups while repelling strangers. In various animals, and particularly birds, specialized visual and auditory mechanisms have a comparable function. Various, the conditions of development favour the effectiveness of such processes and in many ways grouping contributes to species survival.

Striking similarities in social patterning, as between insects and man, encourage analogies as in A. E. Emerson's stress on the social group as supraorganism and his argument that natural selection affects different animal groups in the same ways. Such views can usefully attract attention to comparable organic factors ensuring social life in very different animals, but they also may obscure major differences. In social insects, cuticular secretions, tactual and other factors promote reciprocal stimulation among workers, queen, and brood, unifying the colony; in mammals, including infrahuman primates, the organic products of parturition promote the female's attention to and licking of young; suckling and approach to the female by neonates strongly promote the development of a parent-young bond basic to individual socialization. Yet Schneirla has emphasized the significance of differences in the socialization process itself on different animal levels, terming the insect patterns biosocial, the mammalian patterns psychosocial. In man, although biological factors are basic, their influence in behaviour is far more indirect and complex than in any lower animal.

Analysis shows that, on different levels, comparable biological factors promoting specialization can differ greatly in their developmental consequences, according to phyletic psychological differences such as those discussed in this article. The abiding characteristic of the biosocial level, as exemplified differently by insects and birds, is that organic processes exert their effects rather directly on group behaviour; that of the psychosocial level is plasticity and diversity of outcome according to conditions in development and in the social situation. Whereas the many types of insect social pattern over the world had reached substantially their present forms by Tertiary times, more than 60,000,000 years ago man has passed from the Stone Age to produce complex cultural systems, civilizations, science, and recorded knowledge within the past 50,000 years. Insect social evolution was achieved through organic evolution, whereas man has developed socially within a period when his organic makeup, particularly his cerebral cortex, seems not to have changed in any important respect. Insects have fixed communication patterns, men have plastic symbolic languages; insects have structurally canalized caste functions, men are more likely to have those fixed circumstantially, through social heritage or through differences in intelligence; insects have organically stereotyped forms of cooperation but men are capable of intentional forms of concerted goal striving or of competition according to upbringing and prevalent conditions.

It is not only through his intelligence but also through his emotional potentials that man has succeeded in merging small groups into widespread integrated societies as against the local groups to which all lower animals are held. He has achieved not only vast unitary social organizations, but has become a true international in art, literature, music, and science. Perhaps the most important task of comparative psychology is to show in what respects these achievements are unique and in what respects they are equivalent to the various ways in which lower animals adapt to their worlds. *See also* references under "Psychology, Comparative" in the Index.

PSYCHOLOGY, EDUCATIONAL: see EDUCATIONAL PSYCHOLOGY.

PSYCHOLOGY, EXPERIMENTAL, is a method of studying psychological problems, but the term generally connotes all areas of psychology that use the experimental method. The experimental method as it applies to psychology is a systematic attempt to discover the conditions underlying human and subhuman activities by manipulating variables that may give rise to the behaviour under study; it may investigate the effects of modifying the organism, as well as manipulating external conditions. Like other sciences, it is primarily concerned with discovering laws that describe manipulable relationships (see SCIENTIFIC METHOD).

The areas of study in psychology that lean heavily on the experimental method include those of sensation and perception, learning and memory, motivation and physiological psychology. However, there are experimental branches of most areas including child psychology, clinical psychology, educational psychology, and social psychology. Usually the experimental psychologist deals with normal, intact organisms, but in physiological psychology, studies are conducted with organisms modified by brain or other nervous system surgery, radiation, drug treatment, induced convulsions, or long-standing deprivations of various kinds. The experimental psychologist often finds that his problems overlap those of physiologists, neurophysiologists, radiologists, biochemists, zoologists, pharmacists, physicists, and geneticists. The main line of demarcation between experimental psychology and the closely related fields is the psychologist's emphasis on behaviour.

EARLY PERIOD

Origins.—Experimental psychology as a systematic study grew out of the work of physicists and physiologists who were compelled to recognize the important part played by the observer in results obtained from experiments. Thus it was at first almost entirely concerned with the measurement of reaction times (i.e., the time elapsing between stimulation and response by the observer) and with a study of the special senses.

Major contributions came from Gustav Theodor Fechner (q.v.), appointed professor of physics at Leipzig in 1834, who elaborately sought exact quantitative statements of the relation between the intensity of a stimulus and of the experience it evokes. The methods he initiated were developed to become the foundation of a large part of modern experimental procedure (see PSYCHOPHYSICAL METHODS). In 1885 Hermann Ebbinghaus (q.v.) published the results of a long series of experiments he had made upon himself in the memorizing of nonsense syllables. He claimed that this kind of material made it possible for the first time to experiment successfully on so-called higher mental processes. Near the beginning of the 20th century Oswald Külpe initiated researches on judgment and volition, while from Fechner onward, experimental work on feelings and on such psychophysical problems as fatigue was continued.

In England from the time of Francis Galton statistics received special attention as a method of dealing with experimental results, and experimental psychology was closely in touch with neurology and medicine.

The experimental study of infrahuman animal behaviour (q.v.) is also relatively modern. With a few exceptions, and those for the most part resulting from the interest of comparative anatomists in the localization of bodily functions, the anecdotal method of Aristotle remained predominant in the study of animals till the 19th-century work of Charles Robert Darwin, followed by such investigators as Lloyd Morgan. A flourishing school for the experimental study of animal behaviour arose in the U.S., led by Edward L. Thorndike, Robert Yerkes, and John B. Watson.

Soon every important university in the world recognized the usefulness of experimental method in psychology. Most leading universities provided experimental laboratories and professorships in experimental psychology; journals were established for experimental research in psychology. Organizations arose for the application of psychology, particularly to education and industry.

Perceptual Processes.—The earliest psychological experiments were by physicists and physiologists; consequently a great amount of work in the psychological laboratory concerned such senses as touch, temperature, taste, smell, vision, hearing, and kinesthesia. In studying visual function, for example, disks of different colours may be rotated so rapidly that the resulting experiences combine and the effects of mixing colours in varying proportion can be accurately determined. Special apparatus demonstrates the after-effects of continued light stimulation, and the occurrence of colour-blind or colour-weak zones in the normal eye. A darkroom is used to show the differences between vision in daylight and in twilight and to study abnormalities of colour vision and night blindness. There is special apparatus for controlled exposure of objects: stereoscopes and devices for the study of the perception of solidity or of distance, and of the various optical illusions (see PERCEPTION).

Choice and Feeling.—Subjects of psychological experiment are often asked to judge, to choose, to decide; they commonly report accompanying feelings and emotions. The experimentalist brings into play apparatus by which he can record some of the physiological changes that accompany these processes, such as variation in respiration, in pulse rate, or in glandular secretion. At the same time the subject, acting throughout under relatively controlled conditions, gives a verbal report of what seems to him to have led up to the judgment or the choice. The problem situations may be indefinitely varied in complexity, from the simple judgment as to which of two weights is the heavier to decisions upon controversial questions of great difficulty. (See also FEELING, PSYCHOLOGY OF.)

To measure the speed at which psychophysiological processes take place the psychologist developed elaborate and delicate reaction-time apparatus to determine accurately the time elapsing between stimulation and response.

Especially interesting questions arise in the investigation of abnormal conditions. What, for instance, are the effects of glare or of flicker in the visual field; of excessive and continued noise or vibration in the auditory and tactual fields; of drugs and fatigue generally? The study of fatigue (q.v.) in particular developed a mass of special apparatus and methods, and had an immediate practical application.

Learning and Memory.—After 1920 more experimental psychologists devoted their efforts to studying the intricacies of learning and memory (or retention) than to any other area. The experimental laboratory reflects this interest. For human learning experiments there are tachistoscopes, apparatus for brief visual exposure of verbal or pictorial material, with the length of exposure controlled automatically. There are memory drums for presentation of consecutive learning materials at a fixed, but adjustable, rate. There is a wide range of apparatus for learning motor skills; e.g., the pursuit rotor, complex reaction-time apparatus, a variety of assembly tests, and the two-hand coordinator. In soundproof darkrooms there is highly complex apparatus for conditioning eye-blink response, with both photographic and electronic equipment

for continuous recording of the stimulation and responses.

Apparatus for infrahuman learning includes the straightaway maze, a single, straight alley with a starting box at one end and a goal box at the other; other mazes, shaped like T's or Y's, require a single choice of path, while more complex mazes have from 3 to 10 or even 20 sections arranged with cul-de-sacs (blind alleys). Some of these mazes may be immersed in water so that the animal must swim through the pathways to reach the goal. There is jumping apparatus for training animals to discriminate between visual stimuli, the subject being required to jump from a platform at one of two cards. If the animal jumps correctly, the card swings back and the animal drops into a box containing food; if it errs, it hits an unyielding card and drops into a net. There is apparatus for conditioning animals to withdraw a leg to avoid electroshock. There are revolving drums to record activity and shock apparatus for delivering convulsion-inducing electroshocks. There are Skinner boxes, cages containing a lever which, when operated, delivers pellets of food or drops of water. (See also LEARNING; MEMORY.)

Social Behaviour.—In one direction in particular experimental psychology advanced rapidly. A great many of the conditions of human behaviour are directly social in character and source. Experiments were arranged to allow observation of at least some of the effects of such socially derived motives as competitiveness, pugnaciousness, assertiveness, submissiveness, friendliness, liability to suggestion, leadership, and cooperation.

The earliest success in the social experimental area was with children in college and university nurseries and elementary schools which, from about 1920, served as extensions of the psychology laboratories. Later, successful research in social relationships was conducted with older subjects.

Microphones and one-way vision windows permit experimental observation without detection. Motion-picture and sound-recording equipment have extensively facilitated collection of data. See also PSYCHOLOGY, SOCIAL.

LATER PERIOD

The chief aim of experimental psychology in its early days was a description of experiences as experimentally produced and controlled. Interpretation of results was dominated by theories according to which all complex experiences were made up of unitary sensory elements under the principles of association. Methods were, as nearly as possible, copied from other experimental fields. Particular forms of experience were, as far as possible, studied in isolation; the result was often artificial in the extreme. A need existed to bring the problems of the experimental laboratory much nearer those of real life.

Behaviour.—A powerful influence in bringing about this change was the movement known as behaviourism (*q.v.*). The development of an experimental approach to biology made behaviourism possible. At first, as in the field of general human psychology, experiments with other animals were mainly concerned with the anatomical study of the parts of the central nervous system in which hearing, vision, taste, balance, and the like appear to be mediated.

Then experimenters began to observe how various species of animals learn to discriminate objects or to run a maze. They decided to limit themselves to relating the conditions of their experiments and the behaviour of the animals. It seemed possible to do a great deal without using the notion of consciousness; these experimenters held that to attribute consciousness to an animal is to go beyond directly observable fact. Their success led them to a similar program for experimental work in human psychology.

There was a revived interest in the psychology of the special senses, particularly those of vision and hearing. Memory was investigated less as an isolated type of response and more as falling into place in a whole complex learning process that may continually involve also the activities of judging, choosing, reasoning, and the like. On the side of feeling and emotion increased interest in experiment grew out of work on the effects of the secretions of endocrine glands. Methods of registering emotional expression

through metabolic change were developed. Encephalography was developed in the physiological laboratory and was much exploited by psychologists.

William McDougall emphasized that purposive or goal-directed behaviour could be studied objectively. John B. Watson stressed the importance of objective measurement in psychology, and his book *Behaviorism* (1925; rev. ed. 1930) had a great influence on subsequent experimentalists. Watson conducted researches on emotional learning in children and maze learning in the rat. He stressed the importance of the biological correlates of behaviour.

By 1920 the research of the Russian physiologist Ivan Pavlov was becoming well known in Europe and the U.S., and his influence was doubtless greater because of Watson. Pavlov showed that learning could be studied objectively in the dog. His concept of the conditioned reflex, or conditioned response, remains a formidable method in psychological research.

Theorists.—*Thorndike.*—Important advances in experimentation and theory were being made by Edward L. Thorndike at the same time Watson and Pavlov were at work. Probably Thorndike's most important contribution was his analysis of the role of motivation in human and infrahuman learning. His work was to have great influence, but his interpretation of learning as the formation of specific bonds or connections represented a position of limited generality.

Tolman.—In 1932 Edward C. Tolman published *Purposive Behavior in Animals and Men*, stressing attitudes that typify experimental psychology as conducted in the 1960s. To Tolman, experimental psychology must result from objective measurement and recording. He felt that experimental psychology should seek an understanding of the total, intact organism rather than only the isolated reflexes and underlying neurophysiological processes. He named the total behaviour molar and the underlying psychophysiology molecular. His view that the psychologist's particular domain lay in the study of molar behaviour later received wide acceptance. He emphasized intervening variables: processes which intervene between stimuli and overt responses. Such intervening variables included demand, correlated with some maintenance schedule such as food deprivation; appetite, correlated with appropriateness of the goal object such as a particular food incentive; motor skill, correlated with the type of motor response required; and hypotheses, correlated with the cumulative nature and number of training trials.

Tolman and his co-workers observed sudden changes in learned performance when a preferred reward was substituted for one of lower preference and when an incentive appropriate for a particular drive state, such as food for hunger, was substituted for one inappropriate, such as water. One of his more notable discoveries was that of latent learning, in studies where the animal was allowed to explore a maze in the absence of any extrinsic incentive. When an incentive (*e.g.*, food) was presented at the end of the maze, a sharp improvement in performance was found. Tolman interpreted these data as supporting his position that learning is a process of relating sensory or perceptual processes and that the introduction of an incentive in the latent learning situation does not produce learning but merely provides purpose for performance, the use of previous latent (hidden) learning.

Hull.—Clark Hull beginning in the early 1930s chose physics as a model and developed a theoretical system based on postulates and derived axioms. Unlike Tolman, he did not believe that learning was the result of new stimulus-stimulus connections; rather he conceived of learning as the formation of new stimulus-response connections. Also, contrary to Tolman, he assumed that the operation of incentives and drive states was essential to learning per se and not merely to performance. Indeed, Hull clearly stated that habit strength (*i.e.*, learning) resulted only in the presence of the need reduction which followed reinforcement; reinforcement was defined as the attainment of a reward or the reduction of some deprivation state such as hunger.

In actual operation Hull (as did Tolman) placed great emphasis on intervening variables, and tried to quantify these by determining experimentally the effects of systematic manipulation of the independent variables (*i.e.*, the experimental conditions) on

the dependent variables, the directly measured responses. Hull differed from Tolman in that his primary intervening variables represented a chain of symbolic and complex interacting constructs.

Hull's system stimulated a large group of research projects employing both subhuman and human subjects. The subhuman research, mostly conducted with rats, confirmed that it was possible to establish the effect of many variables such as length of deprivation, delay between presentation of the conditioned and unconditioned stimulus, amount of reward and amount of effort required to obtain the reward. Generally, simple response measures were used, such as speed of running down a straight alley or rate of lever pressing in an otherwise barren box. Hull and his followers stated that the results supported his position that learning is fundamentally the formation of new stimulus-response connections arising from need reduction.

Tolman-Hull Controversy.—Because the Tolman and Hull positions appeared to differ drastically, various attempts were made to establish experimental situations demonstrating that one or the other had the greater predictive power. Hullian theory would predict that all learning is gradual and continuous, whereas Tolman had predicted that some learning, at least, was discontinuous, or saltatory. Neither group, however, was able to control adequately the conditions essential for a definitive test.

A second attempt to establish a definitive test centred around the latent learning controversy, because latent learning is similar to sudden saltatory learning, at least as far as performance is concerned. One of Hull's associates, Kenneth Spence, argued that latent learning could not be demonstrated if all experimental controls were adequate. The large number of experiments which resulted from this controversy demonstrated that latent learning phenomena existed under limited and prescribed conditions but were voided in similar test situations by such conditions as those involving intense deprivation. One result of the latent learning controversy was the realization that wandering around a maze might of itself represent some need reduction.

Hullian theory led to a study of the effect of serial position in memorization of nonsense syllables, analysis of the reminiscence effect (improvement in performance after practice has ceased), and the influence of massed and distributed practice on the serial-position effect. In all cases Hull made predictions on the basis of his postulates, and tested the theoretical curves against those obtained empirically. The general similarities indicated that Hull's system, primarily established on the basis of subhuman experimentation, had considerable power in predicting limited but important aspects of human learning. Another application of Hullian theory is the researches by Spence and Janet Taylor on the effect of anxiety on the conditioned eyeblink response. Making the assumption that anxiety, as measured on a paper-and-pencil test, would function to raise drive level, they predicted that high anxiety would improve performance on simple learning tasks and lower performance on more complex learning tasks. Again, the results gave general support to the predictions.

Others.—Edwin R. Guthrie developed a theory of learning based on conditioned-response principles, and though he did not develop the theory to the point at which many specific predictions could be made, the theory did stimulate the collection of experimental data. Kurt Lewin developed a topological theory using geometric models and physical field theory as illustrative and predictive devices; his technique received attention particularly in experimental social and experimental child psychology. Kurt Goldstein, Max Wertheimer and Norman R. F. Maier independently developed two-factor learning theories that differentiated between so-called conditioned-response type learning and a so-called creative type of learning that has been termed reasoning. Another approach after World War II was the statistical learning theory presented by William Estes and Cletus Burke, and by Robert Bush and Fred Mosteller.

Laboratory Methods.—During the period of 1930 to the 1960s B. F. Skinner and co-workers devised and conducted experiments using a technique in which rate of response is measured instead of errors or latency. Basically this technique in-

involved use of the Skinner box, an experimental chamber bare except for a lever (or multiple levers) and an incentive delivery mechanism. After the animal has been trained to depress a lever and receive a reward, it is subjected to various reinforcing schedules. In a fixed- or variable-interval schedule, rewards are given at predetermined periods of time regardless of the number of lever presses. In a fixed- or variable-ratio schedule, rewards are given after a predetermined number of lever presses, regardless of time.

The Skinner technique proved useful both in the analysis of the effect of motivational states, such as food or water deprivation, and in the analysis of simple learning phenomena; it was, for example, used extensively by Hull and his associates. In the 1960s studies were being conducted on the ability of the subjects to respond to multiple schedules.

Although the technique was used primarily in analyzing rat and pigeon behaviour, it was also used with monkeys and chimpanzees. The breadth of the method was illustrated by the fact that Skinner adapted it for the study of arithmetic instruction among elementary-school children and behavioural analysis of institutionalized mental patients.

The early comparative psychologists studied a wide range of animal species; but a tendency later developed to limit researches to the albino rat. With the establishment of the Anthropoid Experimental Station by Robert Yerkes in 1929 (renamed the Yerkes Laboratories of Psychobiology), there was initiated a series of experiments on the psychobiology of the chimpanzee, including development, sensory function, motives and emotions, social behaviour and learning. Although the Yerkes Laboratories studied other primates only in incidental researches, a beginning was made in the 1930s in the study of other primate species. Carlyle Jacobsen published his ingenious studies on the effect of prefrontal lobectomy on rhesus monkey learning; W. Trendelenberg and W. A. Schmidt, in Germany, studied colour vision in monkeys; in 1933, Heinrich Klüver summarized his work on perception and learning in a wide range of monkey species.

At the same time a primate laboratory was developed at the University of Wisconsin, Madison, under Harry Harlow; by 1945 they had developed standardized techniques for measuring learned behaviour in monkeys. At this laboratory it was found practical to use primates in the same kind of rigidly designed experiments that had been popularized in researches with rats. After 1950 there was an upsurge in the establishment of primate laboratories in the U.S., and psychological research was undertaken at Yale University; Johns Hopkins University, Baltimore, Md.; Emory University, Atlanta, Ga.; the University of Texas, Austin; the University of Oregon, Eugene; the University of Pittsburgh, Pa.; Stanford University, Calif.; the State University of South Dakota, Vermillion; and the National Institutes of Health.

The monkey has a far wider range of trainable behaviour than has the rat. It can solve complex problems on a level of difficulty unapproached by any subprimate form; its speed and proficiency in learning simpler problems make possible far more detailed analysis of the processes underlying learning than is possible with subprimate forms.

Studies at the University of Wisconsin on manipulation motivation and on the rhesus monkey's almost insatiable urge to explore its environment visually made it clear that the monkey's motivational structure is far closer to man's than is that of any other animal except the great apes. This does not imply that other animals lack an exploration drive. Such motives were demonstrated in the rat by David Berlyne in Scotland and by Kay Montgomery in the U.S. The differences between primates and rodents in the form and range of these behaviours is striking, and the limitations of the rat appear to be as pronounced here as they are in the area of learning.

Areas of Interest.—**Learning.**—In the area of human verbal learning there was continuous research on both serial learning, the learning of a series of words or syllables, and paired-associates learning, the learning of pairs of words or syllables. Among the many investigators in this field may be cited the systematic work of Benton Underwood on the effects of distribution of practice.

Underwood found that distribution of practice had a beneficial effect on serial lists of both nonsense syllables and meaningful materials, but that no such effect could be demonstrated for paired associates. Similar research found no evidence for reminiscence with serial lists of nonsense syllables, although this phenomenon had been reported in the past both with serial lists of nonsense syllables and with paired associates.

Thus, the historical inconsistencies from experiment to experiment and from one situation to a similar situation continued to arise. On the basis of a detailed review of the literature, Underwood concluded that there was no single theory such as the reactive-inhibition theory or differential-forgetting theory adequate to account for the existing data. One of the most intriguing contributions in this area in many years was a study by Underwood in which he devised a technique for equating associative strength of both fast and slow learners at the termination of practice. He then tested retention 24 hours later and found no differences between the two groups in terms of response probabilities at recall. If this finding were susceptible to generalization, it would be a solution to the problem of relation between speed of learning and amount retained.

Motor Skills.—During and after World War II major emphasis was given to the development of motor skills tests, particularly as devices predictive of pilot proficiency. A large number of specific tasks resulted, such as the pursuit rotor, the two-hand coordinator, reversed alphabet printing, and block turning. Investigators found that there are multiple variables influencing performance on all these tests, but no new integrating approach to these problems was devised.

From the theoretical point of view, most of the work on motor skills revolved around Hull's concepts of reactive inhibition (i.e., inhibition produced by work) and conditioned inhibition, arising from the fact that stimuli associated with the cessation of a response became conditioned or learned inhibitors. A vast array of experiments was conducted dealing with various motor skills performances under conditions of distributed and massed practice, including the phenomenon of reminiscence. Information on the nervous system locus—peripheral or central—of the inhibitory effects was provided by a number of investigators. Their findings of significant post-rest gain when subjects shift from the active to the passive hand after rest give support to a central locus.

Unlike the results obtained from verbal learning studies, the differences produced by massed and spaced practice on motor skills are enormous, and the phenomenon of reminiscence appears with unflinching regularity. The goal of many investigators was to obtain such precise control over their experimental conditions that they could evaluate precisely the role of reactive inhibition and of conditioned inhibition. Both Underwood and Estes doubted not only the ability of investigators to achieve this, but the theoretical possibility of its being done. Indeed, Underwood expressed skepticism about the existence of the Hullian postulate concerning conditioned inhibition.

Children.—Attention to the experimental study of children, normal and abnormal, was focused during this period on learning studies, and attempts were made to integrate the experimental data uncovered in research on subhuman animals with the developing learning abilities of the child. Most of these studies, such as that of transposition in nursery school children by Margaret Kuenne and the studies by Charles Spiker, emanated from Hull's theory or from Harlow's concept of learning to learn.

Social Psychology.—A renewed interest in experimental social psychology stemmed from the original work of Alex Bavelas, a student of Lewin, on the effects of various communication links on group behaviour. The theory assumes that cooperative action by a group is dependent upon the number and kind of communication links. Various patterns of communication links can be arranged according to definable principles, and their efficiency can be tested on a wide range of task performances by groups of varying size. The effects of different kinds of links on the attitudes of the group members also can be assessed, and the influence of a wide range of conditions, including problem difficulty, distribution of problem-related information, kind of leadership by

selected group members, drug states, and the efficacy of various types of information feedback were investigated. This communication-pattern model became an instrument for the experimental study of the interactions of small- and medium-sized groups.

Perception.—A new approach to the psychology of perception was provided through the researches of Jerome Bruner and co-workers. They were based on the assumption that perception is a selective process and that it will be influenced by the values which the individual places upon selected perceptual objects, whether these values are determined by past affective experiences or by existing internal states. Specific experiments suggested that favourable values accentuate the physical characteristics of objects, such as the size of coins, and that they selectively sensitize the subject's perceptual system and selectively lower his recognition threshold. Unfavourable values, on the other hand, result in perceptual defense, which elevates his perceptual thresholds and increases his latency response. Furthermore, drive conditions (e.g., prolonged periods of food deprivation) may enhance perceptual selectivity. Many of these experiments were subject to criticism on the basis of inadequate experimental controls and failure to control the past experience of the subjects.

In whatever realm and with whatever general background of theory he works, the modern experimental psychologist is definitely committed to a biological method of approach. He regards mental processes as falling into their place in a biological adaptation of the organism to its environment, and his problems are thus becoming more and more an inquiry into the functions which such processes carry out, and less and less merely a description or analysis of the processes themselves (see *PSYCHOLOGY, PHYSIOLOGICAL*).

Modern Practical Applications.—The possibility of applying experimental psychological methods to the solution of practical problems, especially in education, was early realized. The movement gained momentum and extended into many fields of human achievement during World War I when almost every belligerent country called upon its psychologists for advice in the organization and training of its military. In industry psychologists devised and widely applied special techniques for vocational guidance, selection, and training. Time-and-motion studies made notable contributions to human productivity and industrial organization. Fatigue, accidents, and the particular effects upon work of special environmental conditions were studied intensively.

In education the intelligence-test movement grew to enormous dimensions. Medical applications were everywhere exploited, though they were mainly, in this period, confined to the approach through what were called abnormalities. There was even a beginning of experimental investigation of broad problems of industrial management, and there was a burst of interest in the development of new methods for evaluation of public opinion (q.v.).

World War II vastly increased both the amount and the scope of psychological experiment as applied to practical problems. The striking increase of mechanization both in the fighting services and in their attendant industrial processes introduced problems new in magnitude though not in their basic character. In a rapidly increasing number of directions the human operator became an indispensable link in some variety of electrical or mechanical system. Such systems, therefore, had to be devised, and the general and specific conditions of their application determined in accordance with what the normal human individual could be expected to do with the highest efficiency and the smallest strain.

Experimental psychology grew in interest to the physicist and engineer. Further, since mechanization on the whole tends to increase skill requirements, many hitherto unsolved problems concerned with skill training and skill fatigue were effectively studied. With skill training went a tremendous development of synthetic trainers, the principles in the design and use of which had to be considered as never before from the psychological point of view.

Side by side with all this increased interest in problems of the design and control of the instruments and conditions of work was an increase of activity and scope in vocational and professional selection. Even the broader problems of group and individual morale and of the results of the contact of differently organized

social groups began to be approached less from the point of view of dogmatic opinion and more from their factual and partially experimental aspects. (See also PSYCHOLOGY, APPLIED.)

PSYCHOLOGY, HISTORY OF. In psychology, more than any other science, the questions discussed by contemporary writers and the answers they offer cannot be rightly understood without some knowledge of its history. The main problems and the chief types of solution are almost as old as civilization. What has changed are rather the methods of study and the attitudes adopted. Little by little man's thoughts about his nature have developed from the crude speculations of primitive tribes into the traditional myths and dogmas of local theology, then into a topic for critical and philosophical analysis and finally into a systematic branch of natural science, with laboratories, instruments and research techniques of its own. To this progressive evolution almost every civilized nation has made some contribution, varying with race, geography, climate and history.

ORIENTAL PSYCHOLOGY

Early Egyptian Doctrines.—The oldest views about which there are trustworthy documentary records are those of the ancient Egyptians. Their beliefs are of special importance because they exercised a powerful influence on writers of other nationalities who, in their turn, had a more direct effect: history and legend indicate that Moses, Thales, Pythagoras, Socrates, Plato and Herodotus all studied in Egypt. What most impressed those who came into close contact with the Egyptians was their belief in the resurrection of an animated body preserved by mummification. Egyptian religious doctrines, as can be learned from early papyri c. 2300 B.C. onward), were a synthesis of older tribal beliefs and, probably for this reason, their conception of individual personality was peculiarly complex.

Like other primitive thinkers who found it difficult to interpret the concrete in terms of the abstract, they explained the many-sided activities of each human being by referring them, not to distinguishable aspects or components, but to distinct entities, each more or less complete in itself. Physical behaviour was attributed to the material personality, the body or *khat*; this, after mummification, purified by prayer and magical formulae, was transformed into an incorruptible and glorified body, the *sahu*. The conscious activities were referred to the *ba* (or soul), conceived as an invisible and immortal entity, symbolized by a human-headed hawk fluttering from the mouth at death—a pictorial notion doubtless derived from some independent source, since it is hardly consistent with the need for mummification. The man's separable self, the *ka* (his *imago* or double), acted as a kind of protecting genius during life that left him at death but afterward returned: provision for its sustenance had to be made in the tomb. The soul itself was accompanied by a shadow or shade, the *khaibit*. The *khu* (or spirit) was the embodiment of the intellectual attributes. The heart (or rather the *ka* of the heart) was the seat of life and conscience. As the cult of Osiris gained increasing popularity, the belief in a moral judgment after death became more and more prominent: the dead person was conducted to the hall of Osiris, where his heart was weighed against a feather (the symbol of truth); the righteous received rewards, graded according to merit, and the wicked were annihilated. These doctrines with only minor modifications lasted for well over 3,000 years, from the 5th dynasty or before down to Greek and Roman times. And when Alexandria became the world centre for culture and learning they did much to colour the philosophic thought of Hellen-

istic times and of later Christian theology. (See EGYPT: History: Ancient Religion.)

Hebrew Psychology.—Moses (who bears an Egyptian name) was, it is stated, "learned in all the wisdom of the Egyptians." But the Hebrew conception of human personality found in the older Jewish scriptures was far simpler and more akin to that of the other Semitic peoples of Sumer, Babylon and the Arabian desert. In the pre-exilic writings, man was generally depicted as essentially a material structure of bones, sinews and flesh, covered with skin, into which a principle of life has been implanted. As in most Semitic writings, the name of this animating principle is derived from the verb meaning "breathe" (Hebrew, *nephesh*, commonly translated "soul"; cf. Latin *anima*) and conceived as residing in the blood. The words *ruah* ("spirit" or "wind"; cf. Gr. *pneuma*) and less frequently *neshamah* were at first used almost as synonyms. As far as there is a difference, *ruah* suggests life in its dynamic or emotional aspect, as given by God, *neshamah* suggests the specific personality and *nephesh* the animated individual being. The heart is regarded as the seat of intelligence. As in the Babylonian cosmology, the dead were vaguely conceived as passing a silent and shadowy existence in the grave (*sheol*) and could be called up by witchcraft to appear, like Samuel, as bodies fully clothed. The notion of a definite resurrection, confined at first to the righteous, did not appear before postexilic times and seems to have been due largely to Persian eschatology; it is essentially a resurrection of the body. The notion that man is a tripartite being consisting of body, soul (the natural life) and spirit (the divine life), which occurs in Pauline writings, was a relatively late rabbinical doctrine, but even here the conception was quasi-materialistic: after death the individual is still a spiritual body, not a bodiless spirit. But the idea of a *resurrectio carnis*, as affirmed in the "Apostles' Creed," would seem to be contradictory to Pauline views. The conception of an immortal soul, capable of existing apart from the body, appeared only in the late Jewish school of Alexandria and was undoubtedly due to Platonic and Neoplatonic influences. For the rest there is no attempt in Hebrew literature to analyze the capacities or faculties of the soul, as there is in Hindu and Greek writings. Such attempts appear first in the philosophic expositions of Philo (q.v.), who claimed (with little justification) that the three Hebrew terms cited above refer to the three "parts" of the soul as described by Plato.

Hindu Psychology.—From time to time western thought has been appreciably influenced by the cults and philosophies of India. There are, for example, striking analogies between the Orphic and Eleusinian mysteries (see MYSTERY) and the mystical beliefs prevalent at that date in the far east. After the conquests of Alexander, Chaldean astrology, Zoroastrianism, oriental dualism and the religions of India (where Buddhism was becoming supreme) all became familiar to the inquiring mind of the Greeks.

As might be anticipated from their common origin and their common theological and ethical traditions, early Indian psychology shows in its essentials many resemblances to that of the Greeks but, owing largely to geographical and climatic conditions, it tended to become more contemplative and subjective. For this reason the introspective analyses of mental states and processes which it embodies deserve more attention than they usually receive. Almost every variety of theory is to be found, from extreme materialism to extreme idealism and from complete pluralism to complete monism. The most typical doctrines (though not the most orthodox) were those elaborated by the Jainist sages whose teaching goes back at least to the time of the Buddha if not before. Consciousness is regarded as the distinctive characteristic of *jiva*, the "enjoyer" or soul. But the soul is conceived as essentially active, not inactive as in the Sankhya theory. And the doctrine of transmigration, propounded in the Upanishads, fades into the background. Three modes of consciousness are recognized: knowing, feeling and striving (the last two being closely allied). There are five kinds of knowing: (1) direct knowledge, obtained through perception or memory; (2) indirect knowledge, derived from symbols, speech, testimony and the like; (3) knowledge of things at a distance in space or time (*avadhi*, which covers

clairvoyance and pre- and post-cognition); (4) direct knowledge of the thoughts of others (*manahparyaya* or telepathy); and (5) omniscience. Buddhist psychology recognizes a subconscious life (*vidhimutta*) distinct from waking consciousness (*vidhicitta*), which is treated as a process disturbing the flow of subconscious existence; the two are separated by a "door (or threshold) of the mind" (*manodvara*). Here, and in the emphasis placed on analyzing dreams and dreamlike states and on the importance of symbolic interpretation, early Hindu psychology displays many anticipations of later psychoanalytic theories. See INDIAN PHILOSOPHY.

GREEK PSYCHOLOGY

Pre-Socratics.—In the Homeric poems the soul (*psyche*) is a shadowy but still material duplicate of the individual that survives the death of his body. This materialistic view was retained by the early Ionian scientists (600–500 B.C.). Even Empedocles (q.v.; fl. 450 B.C.) regarded man, like everything else in the universe, as made up of four primary elements—fire, air, earth and water—and partaking of their antithetical qualities or states; viz., hot, cold, dry (i.e., solid) and wet (i.e., liquid). In man their presence implies a tension of opposites and the soul is, or should be, a nicely balanced mixture or harmony of the pairs. Perception is also explained in material terms: seeing and hearing, like smell, taste and touch, result from receiving concrete particles given off by the object perceived.

The view that the soul (*psyche*) is a purely immaterial entity emerged first in the doctrines attributed to the Pythagorean brotherhood (c. 500 B.C.). They in turn appear to have been influenced by the Orphic and other mystery cults in which the souls of initiates, by virtue of certain purificatory rites, could be fitted for life after death. Pythagoras (see PYTHAGORAS AND PYTHAGOREANISM) himself believed in transmigration and held that in this life the soul was entombed in the body and obtained release at death. Empedocles (followed by Aristotle and the Stoics) regarded the heart as the seat of consciousness; Alcmaeon of Crotona (q.v.), however, a younger disciple of Pythagoras, contended that the brain was the seat of sensation—a conclusion apparently based on dissection and vivisection, methods that he is said to have used to discover the existence and function of the optic nerves.

Plato.—Greek philosophy took a fresh turn with Socrates (q.v.). According to him, virtue depends on knowledge and this doctrine gave Greek psychology a strong intellectualist bias that was retained in nearly all the later schools derived from it. Plato (q.v.) was the first to raise the problem of consciousness in explicit form. His main contention may be summarized as follows: "We see not with the eyes but through them; we hear not with the ears but through them; hence there must be a common entity which perceives, combines, recalls, and reflects on these sensations"; this, he says, is the soul, which he defines as "a motion that moves itself"; and he adduces a number of arguments to prove that such a soul must be immortal. The different functions that it performs imply that, although a unity, it comprises different parts or powers. And in the discussions that arise out of the questions thus raised he lays the foundations for a new branch of knowledge—psychology, the study of mental life.

In his view the soul includes three main parts or functions: reason, located in the brain; the nobler emotions or spirit, seated in the chest; and the lower appetites arising in the abdominal viscera. Elsewhere he likens the human personality to a chariot guided by a charioteer (reason) and borne along by a pair of horses (spirit and appetite). There is here a clear distinction between the dynamic or motivational components and the directive or "cybernetic" (Plato's own word). In certain individuals one of the three main elements may be more strongly developed than the others and, as a result, the population can be classified according to innate constitution into three distinct classes or castes. As he puts it in a parable, "Gold was mixed in the composition of the born rulers, silver in that of the auxiliaries, and copper or iron in that of the farmworkers or the artisans."

Aristotle.—In his *De anima* (*On the Soul*) Aristotle (q.v.) offered the first systematic treatise on the subject. Because of his

training his standpoint is essentially that of a biologist. The soul is defined as the "form" (i.e., mode of organization) of the body; and by soul he understands, not merely mind, but the principle of life. Every living being is essentially a "besouled body." The fully developed human soul is, as it were, a hierarchical system with three main levels and two main aspects: at the lowest level its functions are purely nutritive, as in plants; at a higher level they are also sensitive, as in nonhuman animals; and at the highest of all it is rational, as in man. In its cognitive aspect the activity of the soul is described as essentially discriminative (diagnostic), whether exercised in simple sensation or in the higher intellectual activities evolved from sensation—imagination, memory and even reason itself; in its appetitive or orectic aspect, its activities include the lowlier functions of moving and desiring, and the higher functions of choosing and willing.

Aristotle's other biological works include an elaborate attempt to interpret both vital and mental processes in terms of what today would be called chemical metabolism, but his chemistry was still based on the Empedoclean theory of four "elements" (i.e., primary principles or states). The qualities of heat and cold were related to active or causal processes and those of dry (solid) and wet (liquid) to relatively passive effects, a distinction that later writers carried over into a doctrine of temperaments. Since the active element in air was believed to be necessary to the production of fire or heat, this aerial or gaseous ingredient, called *pneuma* or spirit (literally "wind"), was held responsible for what Aristotle calls "inborn heat" and thus plays an essential part in the vital processes. Breathing in fact was seen as the typical manifestation of life, while digestion and other vital activities were explained as a kind of internal cookery. The veins were believed to be filled with blood and *pneuma*, and to convey sensations to the heart, which Aristotle regarded as the main sensorium. Since pressing the exposed brains of soldiers wounded in battle produced no conscious effect, consciousness, he argued, could not be located in the brain.

In the psychological theories of the Stoic philosophers (see STOICS) the doctrine of "spirit" explains much that was formerly attributed to the soul; it is now conceived, not as something abstract or immaterial, but as a finer kind of gaseous matter. The earlier Stoics described sensation as an impression made by the object on the mind, much as a seal leaves its impression on wax, but the later Stoics maintained that, in vision, the eye emitted "spirits" that, like rays, illuminated the object—a doctrine accepted by many medieval psychologists.

Greek Medicine.—The most important medical school of the Greek period was that at Cos and its most famous representative was Hippocrates, an elder contemporary of Plato (see HIPPOCRATES). What is known as the Hippocratic corpus was virtually the school's library, copied and preserved by the later librarians of Alexandria. Of the surviving treatises only three or four are as old as Hippocrates and the views put forward are often mutually antagonistic, ranging from the purely empirical to the purely speculative. The best-known formulates the doctrine of humours. In origin this was Empedoclean rather than Hippocratic and was primarily a theory of disease and its treatment: sickness resulted from an excess of cold or heat or dryness or moisture and was to be counteracted by a compensatory regimen aiming at a well-tempered balance of all four.

Herophilus (q.v.; fl. 300 B.C.) dissected the parts of the brain and was the first to recognize the functions of the peripheral nerves and distinguish the motor nerves from the sensory. As a result Aristotle's view was corrected and the brain was henceforward acknowledged to be the central organ of the nervous system and the seat of consciousness. Erasistratus made similar studies of the veins and arteries and elaborated the doctrine of vital and animal spirits into a form it retained until the discoveries of William Harvey.

Of later medical writers the most influential was Galen (q.v.), court physician to the emperor Marcus Aurelius. A voluminous and eclectic writer, he summarized and synthesized earlier views giving them a quasi-philosophical as well as an empirical basis. He practised both vivisection and dissection. In contradiction to

Erasistratus, by a method copied by Harvey, he showed that the arteries contained blood and not air; but his most remarkable studies were in the field of neurology. Severing the spinal cord of a monkey at various points, he demonstrated that both movement and sensation were eliminated below the level of the section.

It was Galen who originated the more familiar form of the theory of four "temperaments." Starting from the traditional doctrine of four basic qualities, he regards the individual's constitution as resulting from what in modern terms would be called his "saturation" for two "independent bipolar factors." The outcome is four distinct types: the choleric (hot and dry), the melancholic (cold and dry), the sanguine (warm and moist) and the phlegmatic (cold and moist). They are distinguished physically by body-build and by hair- and skin-colour and psychologically by their emotional characteristics, which are the effects of the dominant "humour" (yellow bile, black bile, blood and phlegm respectively). With varying terminology and interpretations this fourfold hypothesis survived to furnish the basis of the modern theories of temperamental types, such as those of E. Kretschmer and C. G. Jung (*q.v.*).

The last of the great pagan thinkers was Plotinus (*q.v.*; A.D. 205-270) the founder of Neoplatonism. With him, largely in reaction against the materialistic tendencies of the medical schools, psychology at last became a science of consciousness as such, with introspection as its fundamental method, and the conclusions reached were highly subjective. In order to study the religions of the east Plotinus accompanied the emperor Gordian on his expedition against the Persians; in many points his teaching markedly resembled Vedanta philosophy. He vigorously criticized those who had held that the soul is a material substance or the "form" of a material substance; for him the soul is immaterial and eternal, with its own place in the hierarchy of being. It exists before birth; it survives after death; it may be reborn in another body. During terrestrial life, it can "stand out" of the body in a state of "ecstasy" ("standing out"), a condition that Plotinus himself claimed to have experienced. Probably no philosopher of ancient times exercised so powerful an influence on Christian doctrine during its formative years.

MEDIEVAL PSYCHOLOGY

St. Augustine.—Among Roman authors only Cicero has written works of interest to the psychologist. His influence is due, not to any original contributions, but to his skill in adapting or coining Latin words to transmit Greek concepts to the philosophers of later ages. Much present-day terminology is Ciceronian in origin. After the conversion of Constantine to Christianity philosophy became virtually a branch of theology and most philosophers wrote in Latin. Of the earlier Christian writers, St. Augustine (*q.v.*; A.D. 354-430) was by far the most important. His psychological theories are based on a Platonic or Neoplatonic scheme expressed in Ciceronian terms and his whole doctrine is permeated by a religious mysticism derived partly from the scriptures, partly from Plotinus and partly from personal experience. He reveals exceptional gifts of acute introspection and thus is able to fill in the details of his scheme with firsthand observations. The soul he regards as a simple substance, possessing diverse functions: it is capable of various grades, ranging from the nutritive, sentient, rational, up to the highest of all, a stage of "ecstasy" that yields the fullest form of gnosis or intuitive knowledge of the spiritual world. Its functions are classified on a trinitarian basis into knowing, feeling (or loving) and willing. The cognitive faculties comprise sensation, memory, imagination and understanding; but imagination mediates, not between sensation and memory (as with Aristotle), but between memory and understanding, and is thus given a far more important position than with most other philosophers.

St. Thomas Aquinas.—With the scholastic revival the main task of the leading philosophers was to translate and re-interpret the views of those earlier writers whose teaching could be accommodated to orthodox doctrine. The final synthesis, however, was achieved by St. Thomas Aquinas (*q.v.*; 1225-74), a Dominican. For him it is Aristotle rather than Plato who is *il maestro di*

color chi sanno ("the master of those who know"). An extreme dualism was avoided by defining the soul once again as the "form" of the body, but with the additional and (as his critics held) the somewhat inconsistent qualification that it is also substantial. The basic classification of functions is dichotomous and not tripartite. Within each of the two main aspects there is a hierarchy of levels—with the intellectual functions sharply distinguished from the sensory on the cognitive side and the volitional from the impulsive or appetitive on the conative.

RATIONALISM IN EUROPE

Dualism.—Both on the continent of Europe and in Great Britain the scientific movement that followed the Renaissance was characterized by a vigorous revolt against authority. In psychology the chief innovator was René Descartes (1596-1650). His is one of the great names in what A. N. Whitehead called "the century of genius"—the century that opened with Francis Bacon's *Advancement of Learning* and toward its close witnessed the publication of Isaac Newton's *Principia*. In his *Discourse on Method* Descartes explains how he began by doubting everything—even the existence of any real world, which every previous thinker had taken for granted in one sense if not in another; and yet, he argues, no matter how far I carry my doubts, in the very act of doubting I must be thinking: one thing, therefore, remains beyond all doubt—that I think. On this he bases his famous inference: *cogito ergo sum* ("I think; therefore I am"). He makes a complete division between mind on the one hand and matter on the other. Matter is substance that has extension in space, but does not think; mind is substance that thinks, but has no extension in space. How then does Descartes account for the evident relation between mind and body? In the years that preceded his contributions anatomy had made great strides and he himself had undertaken a special study of the nervous system. The brain consists of two hemispheres and most of its structures are consequently paired; in its centre, however, there is embedded a tiny body, the pineal gland, which has no duplicate. This gland, therefore, must represent the point of interaction: "here the soul impels the spirits toward the pores of the brain, which thus discharges them through the nerves upon the various muscles."

The activities of the nervous system itself Descartes endeavoured to explain as far as possible in terms of mechanical analogies. The chief mechanical wonders of that age were the hydraulic machines that pumped water into the fountains in the gardens of the rich and by an ingenious arrangement of pipes caused lay figures to dance, play musical instruments and even make noises resembling speech. He therefore thought the nerves must be hollow tubes that conducted "animal spirits" and so produced bodily movements; by a "reflected undulation" a wave of animal spirits, released by external stimulation, might rebound from the sensory to the motor nerves and so cause automatic muscular contractions. He drew a sharp distinction between animal behaviour and human behaviour. Animals are machines and nothing more. Human actions are sometimes mechanical, but sometimes they are rational—the result of thought.

In order to understand human behaviour more fully, Descartes later undertook a full analysis of the emotions. They are treated as combinations of six elementary passions: love and hate, joy and sadness, wonder and desire. Their operation is treated as quasi-mechanical, due to the motion of the spirits in the brain and other vital organs; their effects, however, are described as if they were intellectual functions—love, for example, being dependent on expected good, hate on expected evil.

Monism.—Among Descartes' immediate successors the most notable was the Dutch Jew, Benedictus de Spinoza (*q.v.*; 1632-77). Like Descartes he was impressed by the success of a mathematical approach in dealing with mechanics and astronomy; and his *Ethics* is set forth in the style of Euclid, with definitions, postulates and theorems deductively inferred. Descartes' attempt to explain the interaction between a mental soul and a material body was manifestly unsatisfactory. Spinoza's solution was to regard mind and matter, not as two separate substances but as two aspects of one and the same substance which in itself was neutral. This

he termed both Nature and God. For Descartes' psychophysical dualism he thus substitutes a neutral monism. But, he insisted, everything in nature, including a person's own actions, must be ruled by logical necessity; he held that the idea of free will was an illusion resulting from the fact that movement only is perceived, not its cause, and so it is wrongly inferred that the movement must have been self-caused. However, the third part of his book is of greatest interest to psychology. In it he expounded his doctrine of *conatus*: "everything, in so far as it is in itself, strives to persevere in its own being." Self-preservation is the basic motive and the emotions are reduced to a tension of opposing tendencies, with joy and sorrow as the most elementary feelings. The operation of the emotions may thus be both irrational and unconscious, but "a passion which is evil ceases to be a passion as soon as we form a clear and distinct idea." Here there is a remarkable anticipation of the doctrines of a later Jewish psychologist, Sigmund Freud.

Monadism.—To escape from the difficulties raised both by the dualism of Descartes and the monism of Spinoza, G. W. Leibniz (*q.v.*; 1646–1716) suggested that the universe consists of a hierarchy of monads, *i.e.*, units which are essentially psychical but may also possess certain physical properties. The human body, for example, is a system of more or less inferior monads with one dominant monad, corresponding to what would ordinarily be called the soul. There is no real causal interaction: the appearance of causation is due to a "pre-established harmony" or parallelism between the changes in one monad and those in the others—like that of two or more clocks keeping similar time. Even the inferior monads are supposed to be capable of *petites perceptions*, *i.e.*, unconscious "prehensions" (in Whitehead's phrase); when these become clear and explicit in fully conscious apprehension, the process is described as apperception—a new term that, with varying interpretations, plays an important part in later theories.

With Christian Wolff (*q.v.*; 1679–1754) the rationalist attempt to base psychology on purely deductive arguments reaches its climax. The basic principles were mainly those of Leibniz, but Wolff developed the Aristotelian notion of a scale of faculties into a systematic hierarchical scheme. He began with the double dichotomy of the scholastic philosophers: mental "powers" are divided first vertically (as it were) into cognitive faculties and appetitive (or orectic) propensities; each set is then divided horizontally into lower and higher powers; *i.e.*, into perceptual or conceptual processes on the one hand and into involuntary or voluntary processes on the other. The more specialized functions are then classified under these various heads.

BRITISH EMPIRICISM

The Revival of Materialism.—Throughout the middle ages the atomistic doctrines of Leucippus, Epicurus (*q.v.*) and their followers were almost wholly neglected because of their antireligious tendencies. In the middle of the 17th century, however, the French mathematician, Pierre Gassendi (*q.v.*; 1592–1655) attacked both Aristotle and Descartes and revived the atomistic theory. In Great Britain a similar materialistic view was adopted by Thomas Hobbes (*q.v.*; 1588–1679), who pushed it to further extremes. A friend and follower of Francis Bacon, he held with Bacon that experience is the only source of knowledge and, in his most famous work, *The Leviathan*, maintained that experience was based on sensation and that sensation, like all other phenomena, was reducible to motion: "'tis but an apparition of that motion which the object worketh in the brain." Hobbes's revolutionary doctrines aroused little interest until the reappearance of materialist theories during the 19th century. Thus the effective founders of British empiricism were the three great writers who followed him, John Locke (1632–1704, an English physician), George Berkeley (1685–1753, an Irish bishop) and David Hume (1711–76, a Scottish man of letters) (*q.v.*).

Locke's conclusions are always in keeping with those of common sense. In his *Essay Concerning Human Understanding* he borrows from Descartes (whose writings first "gave him a relish of philosophical things") the doctrine that matter and mind are two distinct substances, but he diverges from Descartes in rejecting the

notion of "innate ideas." His method too, unlike that of Descartes, was that of induction (in the Baconian sense) rather than Euclidean deduction; he even, when discussing sensory phenomena, cites the result of an *ad hoc* experiment. In introducing what he calls "the new way of ideas," he starts by urging that the mind should be regarded as being at the outset simply "as it were white paper, void of all characters." Whence then come the materials of reason and knowledge? To this he gives the same answer as Bacon and Hobbes: "in one word from experience." Experience, he holds, is of two kinds: it comes partly from sensation and partly from reflection, which he describes as a kind of "internal sense." Ideas are likewise of two kinds: simple and complex. Simple ideas are thus treated as elementary atoms of consciousness that combine to form more complex states. They may have either primary or secondary qualities, but the former alone reproduce the qualities of external objects. While denying innate ideas, he admits that the mind has innate powers. But these powers must be regarded merely as names for the various ways the mind can act and are not to be treated, in the fashion of the scholastics, as ultimate causes.

Berkeley's earliest work, *An Essay Towards a New Theory of Vision*, studied a specific problem in psychology in and for itself; and his novel conclusion is that the appreciation of distance is not (as had previously been supposed) a direct visual perception but the effect of earlier associations with experiences of touch and movement. In his *Treatise Concerning the Principles of Human Knowledge* and *Three Dialogues Between Hylas and Philonous* he carries Locke's premises to their logical conclusion, arguing that the primary qualities of sensation are just as subjective as the secondary. There is thus no factual evidence whatever for the existence of material substances such as hitherto had always been postulated as the causes of ideas, but on the other hand he still assumes the existence of mental substances as the unobservable but logically necessary bases for conscious experience.

Hume's *Treatise of Human Nature*, as its title page explains is "an endeavour to introduce the experimental method of reasoning into moral subjects": (by "moral" subjects he means "psychological" and by "experimental" reasoning the method of inductive reasoning based on "experience and observation" with a minimum of presuppositions, the method Newton had used in expounding his system of the material universe). And in the principle of association he believed he had found "a kind of attraction in the mental world" that would have the same explanatory possibilities as the principle of gravity in "the natural world." He treats Berkeley much as Berkeley had treated Locke and the arguments that discredit the notion of a "material substance" are turned against the assumption of a "spiritual substance." Book I of the *Treatise* deals with intellectual processes. Mental contents are divided into two main groups: "impressions" and "ideas." Images, it is said, differ from impressions solely by being less vivid. Relations are recognized as a special group of "complex ideas" and a classification of relations is proposed that is a definite improvement on Locke's. The course of thinking is determined by three types of association: by resemblance, by contiguity in space or time, and by cause and effect. Book II discusses "the passions" on somewhat similar lines. Two classes are recognized: (1) the direct affections, which are reduced to terms of three bipolar factors—joy and grief, desire and aversion, hope and fear; and (2) the indirect affections, which involve an associated object as well as a cause and thus resemble what were later called sentiments.

David Hartley (*q.v.*; 1705–57) in his *Observations of Man* reduced the association of ideas to a purely physiological association. The nerve fibres, he suggests, are not "hollow tubules" but "solid capillaments" and the "vibrations" they conduct can set up permanent connections in the brain between the centres for "ideas." The greater part of his book is an ingenious attempt to explain the whole of mental life in terms of this neurological principle.

In France Voltaire (*q.v.*) did much to popularize the ideas of Newton, Locke and other English writers. A completely mechanistic view of mental life, based on oversimplified sensationalistic and associationistic conceptions, was elaborated by J. O. de La-

metrie (*q.v.*) in *L'homme machine*, by his young contemporary E. Condillac (*q.v.*) and by physiologists like M. F. X. Bichat, P. J. G. Cabanis and P. H. T. d'Holbach. The result was a remarkable anticipation of modern behaviourism.

REALISM, IDEALISM AND ASSOCIATIONISM

Scottish Faculty Psychology.—The reaction against these more extreme types of skepticism and materialism took the form of a return to a common sense realism in Scotland and a transcendental type of idealism in Germany. The first revolt against the mechanistic tendencies of the sensationalist school came from the Scottish universities. In his *Essay on the Intellectual Powers of Man* Thomas Reid (*q.v.*), the founder of the Scottish school, endeavoured to counteract the phenomenalism to which the sensationalist theories were tending by developing a "new realism founded on the common sense of mankind." The result is a revival of a psychophysical dualism; but, in seeking to re-establish the hypothesis of a soul, his arguments are no longer based on the old deductive procedure but on the type of inductive reasoning introduced by the empiricists themselves. In particular, he and his chief expositor, Dugald Stewart (*q.v.*; 1753–1828), revived the traditional doctrine of "mental powers" and produced a classified list of 36 or more, most of which were later taken over by the phrenologists, and so came to furnish a ready-made vocabulary for educational and medical writers and even for biographers and novelists. Thomas Brown (*q.v.*; 1778–1820) incorporated the principle of association by interpreting it not as a physiological mechanism but as a mode of mental activity, which he renamed "suggestion"; his treatment is noteworthy for his detailed formulation of both primary and secondary laws of association and for his theory of "relative suggestion" (the "eduction" of analogies or correlates). Finally, Sir William Hamilton (*q.v.*; 1788–1856), a man of encyclopaedic erudition, went a step further and claimed that all forms of "association" were merely special cases of what he called "redintegration," *i.e.*, reinstating ideas. His main aim, however, was to combine the tenets of the Scottish school with those of the new idealistic movement in Germany.

The Rise of German Psychology.—Immanuel Kant (*q.v.*; 1724–1804), who had been brought up on the Wolfian version of Leibniz' theories, relates how at length a study of Hume "woke him from his dogmatic slumbers," and in the end he evolved a "transcendental" philosophy from a synthesis of Leibniz, Wolff and Hume. His insistence on the "synthetic unity of apperception" struck at the heart of the sensationalist and associationist interpretations; and, by distinguishing the "transcendental ego" from the "empirical or phenomenal self," he relegated empirical psychology to a branch of anthropology. Indeed, it is not so much in his better known *Critiques*, but rather in his *Ethics* and his *Anthropologie in pragmatischer Hinsicht* that his chief contributions to psychology are to be sought. Here he works out the threefold division of mental functions into knowing, feeling and willing, in place of the twofold classification favoured by the faculty psychologists, and sketches a theory of temperamental types. In *Träume eines Geistersehers* ("Dreams of a Spirit-Seer") he had already revealed an interest in paranormal phenomena and an appreciation of the importance of inductive methods in the study of mental life. In the end he concluded that, since all science is essentially mathematical and since mathematical methods could not be applied to the study of mind, psychology could never become a genuine science. As a result the interest of his work for the psychologist lies more in his criticisms than in his discoveries.

The aims of J. F. Herbart (*q.v.*; 1776–1841, Kant's successor at Königsberg) were expressed by the title of his textbook—*Psychologie als Wissenschaft neu gegründet auf Erfahrung, Metaphysik, und Mathematik* ("Psychology as Knowledge Newly Founded on Experience, Metaphysics and Mathematics"). The inclusion of *Mathematik* is Herbart's answer to the challenge of Kant. He rejects the whole concept of faculties, and regards mental life as the manifestation of elementary sensory units or presentations. These he conceives as mental forces rather than as mere "ideas" in Locke's sense. The study of their interactions gives rise to a statics and dynamics of the mind, to be expressed

in mathematical formulae like those of Newtonian mechanics. Ideas need not be conscious; and they may either combine to produce composite resultants or conflict with each other so that some get temporarily inhibited or repressed "below the threshold of consciousness." An organized but unconscious system of associated ideas forms an "apperception mass"; such a system could apperceive a new presentation and thus give it richer meaning. On this basis Herbart later developed a theory of education as a branch of applied psychology and so became the "father of pedagogy."

Associationism.—In England the principles of association outlined by Hume, Hartley and Brown found their most rigorous and complete exposition in the theory developed by James Mill (*q.v.*; 1773–1836). In his *Analysis of the Phenomena of the Human Mind* he describes "sensations" and "ideas" as the two "primary states of consciousness"; these were mechanically linked by association, now reduced to a single principle—"order of occurrence." Its strength is determined by two main conditions—frequency and vividness. To this simple doctrine he added the hedonistic theory of his friend, Jeremy Bentham (*q.v.*): human actions are motivated solely by pleasure and pain. His son, John Stuart Mill (*q.v.*; 1806–73), adopted as his scientific model, not the physics of Newton, but the chemistry of John Dalton. He accordingly modified the mechanical theory proposed by his father, arguing that the "elements" into which consciousness could be analyzed were combined by a kind of "mental chemistry," so that the compound, instead of being just the sum, mixture, or mere resultant of the parts, had novel properties of its own. But the most stimulating of his contributions was his discussion in the closing book of his *System of Logic* of the methodology appropriate to psychology.

RISE OF EXPERIMENTAL PSYCHOLOGY

The Physiology of the Nervous System.—In 1810 F. J. Gall (*q.v.*), a German anatomist, began to issue a lengthy treatise claiming to localize the various faculties of the mind in specific parts of the brain, thus furnishing a diagnostic technique for individual psychology. For various reasons the doctrine became as repugnant to the scientist and the philosopher as it was popular with the general public. Its most effective critic was M. Flourens (*q.v.*), who in 1824 published a series of experimental studies of the brain (chiefly in pigeons) in which he showed by extirpating different parts that each had an *action commune* (a general activity shared by the remaining parts) as well as an *action propre* (a specific action peculiar to itself), the chief emphasis being on the former. In 1825 J. B. Bouillaud, on the basis of clinical evidence, localized a centre for speech in the frontal convolutions of the brain, confirmed by P. Broca's more careful work in 1861. This was followed by the localization of motor and sensory functions by G. T. Fritsch and J. E. Hitzig and others in the second half of the century. In Britain as early as 1811 Sir Charles Bell (*q.v.*) had definitely proved by severing the spinal roots the sharp distinction between the sensory and motor functions of the peripheral nerves; and about 20 years later J. Müller provided experimental evidence for the hypothesis of reflex action and formulated what he called "the law of specific energies" (that each sensory nerve can convey only one sensory quality) (see MÜLLER, JOHANNES PETER). During the same period improved microscopical methods had enabled the histologists to demonstrate that the grey matter of the brain and spinal cord alone contained "nerve-cells" while the white matter consisted solely of "nerve-fibres," and that every fibre was connected with a cell—a neural structure that seemed to fit admirably with the requirements of associationist theories.

Alexander Bain (*q.v.*; 1818–1903) was the first to emphasize that "the time had come when the new discoveries of the physiologists should find an appropriate place in the Science of the Mind"; and his two volumes—*The Senses and the Intellect* and *The Emotions and the Will*—provide by far the best survey of mental processes as studied by purely observational methods before psychologists themselves had begun to carry out systematic experiments. The basis of his account is a hypothesis of psychophysiological parallelism, which long remained the most popular solution

to the body-mind problem; as he expressed it, "no nerve-currents, no mind." But, unlike earlier associationists, he fully recognized the importance of the innate tendencies (reflexes and instincts) and laid far greater stress on movement and activity.

The Experimental Study of Sensation.—Galileo's discovery of the dependence of audible pitch on the frequency of the vibrations and Newton's discovery of the laws of colour mixture marked the beginnings of a realization that sensory experience is systematically related to the physical characteristics of the stimulus, but little progress was made until the early 19th-century anatomists began to investigate the structure of the various sense organs.

The first step consisted in the collection of factual data by methodical observation. In 1801 Thomas Young (*q.v.*; 1773–1829) published his trichromatic theory of colour vision, which later obtained strong support from the experimental studies of H. L. F. von Helmholtz and W. McDougall (*qq.v.*). An attack on the Newtonian theory by the poet Goethe in his *Zur Farbenlehre* stimulated J. E. Purkinje (1787–1869) to publish two series of observations on colour sensation (particularly under conditions of night-vision). A new line was opened up by the experiments of E. H. Weber (*q.v.*; 1795–1878) on touch-sensation, which included the demonstration that the physical intensities of stimuli which are just noticeably different in their perceived intensities bear a constant ratio to each other.

G. T. Fechner (*q.v.*; 1801–87) studied medicine under Weber and, after making his reputation by measuring electrical currents, was appointed professor of physics at Leipzig. Shortly after, in a work entitled *Zend-Avesta* (an attack on materialism) he published his program for psychophysical research; this was based on a philosophical theory (derived in his case from oriental sources) that matter and mind are two complementary aspects of the universe, whose relations can be expressed mathematically by what is known as the Weber-Fechner law. Still more important are his three "psychophysical methods" (1860). In later years he devoted his attention to quantitative studies of artistic appreciation and may thus also be regarded as the founder of experimental aesthetics.

It was, however, Helmholtz (1821–94) who made the most important factual contributions to experimental psychology. He was the first to make experiments on reaction times and determine the rate of conduction in nerves. His hypothesis of "unconscious inference" and his defense of empiricism provided topics of controversy for many years. His four great volumes on physiological optics and tonal sensations and the theory of music formed standard works of reference for more than half a century.

W. Wundt (*q.v.*; 1832–1920) founded the first laboratory of psychology (1879) and the first journal of experimental psychology (1881) and was for 40 years the most influential figure in scientific psychology: his *Grundzüge der physiologischen Psychologie* remained a basic textbook until well into the 20th century. Essentially a systematizer, he brought together a wide array of facts into a more or less coherent scheme: psychology, according to Wundt, shows how experience can be analyzed into specific elements ("sensations," with their various "attributes") and how, by a process of "creative synthesis," they can be combined into "psychic resultants" and what are the laws of combination. This was later supplemented by a tridimensional theory of feelings, with three independent bipolar components combining, like physical forces to yield "resultants."

Evolutionary Psychology.—In his "synthetic philosophy" Herbert Spencer (*q.v.*; 1820–1903), "the last of the associationists and the first of the evolutionists," set out to depict evolution as the key to both inorganic and organic nature. Evolution he conceived as proceeding, by a double movement of analysis and synthesis—of "differentiation" accompanied by "integration," toward an ever-increasing adjustment of the individual organism to its external environment. Biology, as the science of life, applies these principles to the general development of living organisms, and psychology, as the science of mental life, applies them to mind, thus becoming itself a branch of biology rather than a mere branch of philosophy or physiology. These theories formed the basis of

his *Principles of Psychology*. Here, adopting the ideas of the neurologist John Hughlings Jackson (*q.v.*), he treats the sensorimotor reflex as exhibiting in its simplest form the general pattern of all mental activity; and, as the nervous system progressively differentiates into a hierarchy of sensorimotor mechanisms of increasing complexity, so the general capacity for adaptation, which Spencer calls "intelligence," was said to differentiate into increasingly complex and specialized capacities for adaptive reaction. In his *Principles of Sociology*, he applied the same interpretative principles to the growth of human societies and laid the foundations for what subsequently became known as "social psychology."

The supreme achievement of Charles Robert Darwin (*q.v.*; 1809–82) was to collect a vast array of factual evidence supporting the hypothesis of "natural selection" as the chief mechanism underlying the process of evolution. His *Origin of Species* thus transformed the idea of evolution from a speculative concept into an established theory. In *The Descent of Man* and *The Expression of Emotions in Man and Animals* he further proved that not only the physical attributes of man but also his "intellectual, emotional and moral faculties" have evolved from those of lower animals and obey the same laws of variation and heredity. His researches on infant development and animal learning paved the way for two further branches of what Spencer had called "comparative psychology"—child and animal psychology.

Sir Francis Galton (*q.v.*; 1822–1911), a half cousin of Darwin, is universally acknowledged as the founder of individual psychology as a genuine branch of science. The phrenologists had raised the problem; but their methods were anything but scientific. Galton introduced a wide variety of techniques: mental tests, psychological questionnaires, anthropometric surveys and the basic methods of statistical analysis. He and his co-worker, Karl Pearson, were the first to apply correlational procedures to the analysis of mental capacities into their elementary components or "factors." It was Galton, too, who led the way in applying Darwin's twofold principles of heredity and variation to the interpretation of individual differences. His work on *Hereditary Genius* established the pedigree method as a useful means of studying mental endowment and his *Inquiries into Human Faculty and its Development* summarized his investigations on mental imagery, free association, the resemblances of twins and his final conclusions on nature, nurture and eugenics.

Neoscholastic Psychology.—In opposition to the materialistic theories of the physiological associationists, who had claimed to reduce consciousness to a mere succession of nerve currents in the brain, there was during the last quarter of the 19th century a new and growing interest in the older "analytic" approach of the medieval philosophers. F. Brentano (*q.v.*; 1838–1917) revived the scholastic doctrines of "intention" and "inexistence," basing them, however, on an empirical study of introspective data rather than on philosophic argument. In his view the distinctive characteristic of a conscious process or act was that it always "intended" (*i.e.*, referred to) an immanent or "inexistent" object beyond itself. The Polish philosopher, K. Twardowski, further distinguished between "content" and "object"; and A. Meinong (1853–1920, Brentano's ablest follower and founder of the first psychological laboratory in Austria) developed the theory that consciousness involves three terms: a process or "act" (*e.g.*, perceiving), a "content" (*e.g.*, a sensum such as "yellow") and an "object," which might be either existent (*e.g.*, a yellow "thing") or subsistent (*e.g.*, a "class," a "relation" or a "fact"). In 1890 C. von Ehrenfels (*q.v.*) published a detailed account of what he called the quality of a shape or form (*Gestaltqualität*), a concept already adumbrated by E. Mach (*q.v.*), the Viennese physicist, who regarded both spatial shape (*e.g.*, a circle) and temporal form (*e.g.*, a melody) as "sense impressions." Such "qualities," it was held, may arise out of relations between "fundamentals" but are quite independent of them—an assertion later attacked by C. Spearman. The so-called Austrian school had numerous adherents, highly influential in their day (notably C. Stumpf, who substituted the conception of "function" for that of "act," and T. Lipps whose best known contribution was his theory of "empathy"), and prepared the way for the Würzburg and Gestalt schools of the 20th century.

Functional Psychology.—A similar revolt against the crudities of the materialistic doctrines of their day took place in Great Britain and the U.S. The associationists had approached psychology from an intellectualistic standpoint and were chiefly concerned with analyzing the mind into sensory elements and describing its structure. The theory of evolution led naturally to a study of mind from a more practical standpoint, emphasizing function rather than structure and preaching a dynamic rather than a merely analytic psychology. The leaders of this new movement were William James in the U.S. and James Ward in Britain.

James Ward (1843–1925) opened the attack with his celebrated article on "Psychology" in the 9th edition of the *Encyclopaedia Britannica* (1886). Mental activity, he argued, must imply a mental agent. This he termed a "subject" (in the Kantian sense) and, following Kant, he insisted that all mental activity had a threefold aspect, affective and conative as well as cognitive or intellectual. Instead of sensations he preferred to speak of "presentations" (ways in which the cognized object is presented to the subject) and instead of analyzing conscious contents into atomistic elements he maintained that consciousness was essentially unitary and continuous.

James Sully (1842–1923), a lucid exponent with a more eclectic but less original outlook than Ward, sought to amalgamate the new doctrines with what was sound in the old and give the results a more systematic shape, largely with a view to applying them to practical problems such as individual differences, child development, abnormal psychology and education. He had studied under Helmholtz and, impressed with the possibilities of the new experimental techniques, opened at University college, London, the first psychological laboratory in Britain (1896). There he worked in close collaboration with Galton and K. Pearson and established in his education department a kind of child guidance clinic for the study of normal and abnormal children.

His *Outlines of Psychology* and his two volumes on *The Human Mind* became the most popular textbooks of their time. Psychology, he maintains, includes the investigation both of mental functions and of mental elements or contents (the sense data and images mediating between the knowing mind and the object presented or known). Functions and contents imply corresponding potentialities (which he referred to as "factors") varying in strength with different individuals. There are three main functions—cognition, affection and conation—and three main types of content, arranged in developmental levels of increasing specialization and complexity—perceptual, reproductive and conceptual. The basic mental processes—appearing in all functions and at every level—are "discrimination" (mental analysis) and "integration" (mental synthesis), of which association was but one specific form.

G. F. Stout (q.v.; 1860–1944) combined the standpoint of Ward with the teaching of Herbart and the Austrian school. His most original and most influential work was his *Analytic Psychology*. Though interested chiefly in problems of cognition, he consistently emphasized the importance of conative activity in all intellectual processes and thus laid the foundations for the more dynamic type of psychology advocated by W. McDougall, R. S. Woodworth and their contemporaries. The distinctive result of mental activity Stout regards as integration or organization into systems ("noetic synthesis" as he preferred to call it): perception, association and the "reduction of relations and correlates" (to use the later description) are merely special manifestations of this more general principle.

William James (q.v.; 1842–1910) is generally regarded as having been the greatest U.S. psychologist. His *Principles of Psychology* re-interpreted the facts of physiological and experimental psychology in the light of an unceasing insistence on consciousness as something personal, continuous and purposive. In consequence he too became a vigorous critic of the atomism and the mechanical associationism of the older schools, expounding his views with literary brilliance and felicity. He established a laboratory (for demonstration rather than research) almost as early as Wundt. He was an ardent advocate of the interactionist interpretation of the relation between body and mind and by his active interest in unconventional studies, such as hypnosis, religious experiences and

psychical research, did much to render these topics scientifically respectable. In his later years his lively and often paradoxical criticism of contemporary theories laid the foundation for both the "functionalist" and the "neo-realist" schools that developed in the U.S. during the early years of the 20th century. (Cv. B.)

PSYCHOLOGY IN THE 20TH CENTURY

From its earliest days the 20th century held great promise for psychology. Under the impetus of its own achievements in the 19th century, and in partnership with mathematics, medicine and other burgeoning disciplines in the physical and biological sciences, psychology advanced both scientifically and professionally. By the 1960s departments of psychology were firmly established in colleges and universities throughout the world, training scientists and practitioners whose contributions were increasingly in demand by governments, businesses and the general public. This rapid proliferation has been relatively quite recent. In the last half of the 19th century, notwithstanding its increasingly experimental and practical features, psychology was still commonly considered a subdivision of philosophy. Wundt, for example, in order to publish the results of his experiments founded a periodical he apparently was constrained to name *Philosophische Studien*; and, since there was no precedent for a chair of psychology at the University of Leipzig, he carried on officially as professor of philosophy.

The tendency of psychologists to identify themselves with particular systems or schools was passing in the 1960s. Instead, contemporary psychologists are likely to adopt such identifications as learning theorist or clinician or psychophysicist, stressing a particular problem or area of application. However, the advance of scientific psychology in the early decades of the 20th century was powerfully influenced by three major schools or movements: behaviourism, Gestalt psychology and psychoanalysis, all three flourishing against a background of activity already well in ferment at the turn of the century. For detailed histories of the growth of these movements and of how they contributed to modern psychology see BEHAVIOURISM; GESTALT PSYCHOLOGY; PSYCHOANALYSIS.

The emergence of specialized topics in scientific psychology as more or less well-defined subdisciplines with their own corps of investigators, theorists and histories has tended to characterize the period from the 1930s to the 1960s. These developments are traced in such articles as PERCEPTION; EMOTION; MOTIVATION; LEARNING; INTELLIGENCE; PERSONALITY; PSYCHOLOGY, EXPERIMENTAL; THINKING AND PROBLEM SOLVING; PSYCHOLOGY, SOCIAL.

Aside from its considerable progress as a pure science in the 20th century, psychology gave substantial evidence of increasing professional maturity. The professional development of psychology is indicated by its widespread acceptance as an independent science with applications to many aspects of daily living. From the beginning of the century many psychologists began to move toward an interest in problems arising in education, vocational selection and placement, or personal and social interrelations in a wide variety of contexts. As a result, psychology has taken its place among the service professions by developing and employing psychological tests and measurements, counselling and psychotherapeutic techniques and applications to engineering, especially for the purpose of adjusting man-machine relationships in military and industrial settings. The history of such efforts is selectively presented in PSYCHOLOGY, APPLIED; PSYCHOLOGICAL TESTS AND MEASUREMENTS; EDUCATIONAL PSYCHOLOGY; PSYCHIATRY; PSYCHOTHERAPY; PUBLIC OPINION.

PSYCHOLOGY, PHYSIOLOGICAL, is the study of the physical basis of behaviour. Primarily it is concerned with how the brain and the rest of the nervous system function in activities (e.g., thinking and perceiving) recognized as characteristic of man and the other animals. Because the nervous system critically depends upon other organs of the body for its normal function, physiological psychology also is concerned with the mechanisms of metabolism, the elaboration of hormones by the endocrine glands, and other regulations of the internal environment. Furthermore, the structural and functional characteristics of the nervous system, as well as of other organs, are mediated by the mechanisms of heredity and are affected by diet, drugs, and disease. Thus, behaviour may be influenced by all of these things, for the nervous system is the major proximate agent of the behaviour of most animals.

Although the early philosophers did not understand the nervous system very well, they knew that psychological activities were in some way related to the body and its functions. Thus the historic roots of physiological psychology lie in the classical mind-body notions of philosophy (see **BODY AND MIND**). Aristotle's view of this dispute, known as the double-aspect theory, was that mind and body were different aspects of the same thing, that body was the structure and mind the function. This surprisingly modern view did not entirely satisfy many others, however. René Descartes, for example, was impelled to reserve soul as the realm of the mind of man. He denied mind in animals and viewed their behaviour completely mechanistically, ascribing it entirely to the functioning of the brain and its nerves. For man, however, he argued that while basic reflexes were mechanistically determined, mind was a separate spiritual (immaterial) entity. To explain how mind and body could influence each other he proposed an interaction theory, holding that the site of the interaction between mind and body was the pineal body in the brain.

Even more independence of mind from body was envisaged by G. W. Leibniz in his theory of psychophysical parallelism. Leibniz maintained that mental events and bodily events occurred in two separate realms, entirely independent but nevertheless paralleling each other perfectly, as though in accordance with a predetermined plan.

In modern history, the behaviourists under J. B. Watson tried to carry the solution of the problem one step beyond Descartes by denying the existence of mind in man as well as in animals and by embracing a monistic, deterministic philosophy. They tried to strike all mentalistic terms—mind, consciousness, and feelings—from scientific use and spoke only of observable behaviour, which they believed was the biological outcome of the activity of the nervous system (see **BEHAVIOURISM**).

Although mind is still more difficult than overt behaviour to define and specify scientifically, there is actually no need to exclude the term mind when it is useful to designate certain real, if ill-understood, aspects of man and his experience. Scientifically, however, mind cannot be used to refer to the nonphysical (since science is limited to phenomena; i.e., the physical) despite the great emphasis that philosophical and cultural heritage has placed upon the spiritual. Physiological psychology begins, then, with the basic concept that if the word mind is to be used, it is to be understood in such terms as the activities of the nervous system.

Basic Properties of the Nervous System.—The anatomy and physiology of the nervous system are given in detail in the articles **BRAIN**; **SPINAL CORD**; **NERVE**; **NERVE CONDUCTION**; and **NERVOUS SYSTEM**. Only a brief review will be given here.

Grossly, the nervous system consists of the brain and spinal cord and their nerves. Sensory nerves deliver impulses to the spinal cord; motor nerves leaving the cord go out to the muscles and glands. This provides the basis for reflexes such as the automatic withdrawal of a leg from a painful stimulus (see **REFLEX**). In addition, the incoming sensory nerves send impulses up to the brain, and the brain in turn sends motor impulses down to the segments of the spinal cord. At various levels in the brain, the

incoming sensory nerves are linked by multitudinous connections to the outgoing motor nerves, making up an infinitely complex mechanism for the integration of behavioural functions, similar in principle to the reflex mechanism.

To understand these connections and their importance in behaviour, it is necessary to appreciate the gross morphology of the brain and its function (see fig. 1 and 2). The continuation of the spinal cord into the brain is called the medulla; it contains, in addition to the major sensory and motor pathways and integrating mechanisms, many groupings of nerve cells that mediate such functions as respiration and circulation of blood. Above the medulla is the midbrain, serving in many simple visual and auditory reflexes. Behind the medulla and midbrain lies the cerebellum, concerned primarily with coordination of posture and locomotion. The thalamus, situated above the midbrain, mediates the integration of incoming sensory nerve impulses and relays sensory impulses to the cortex. Below the thalamus is the hypothalamus, concerned with control of the pituitary gland and such complex functions as water balance and thirst, sleep, food ingestion, reproduction, and emotional expression. Above the thalamus are the two cerebral hemispheres so prominent in man. The main mass of these hemispheres consists of white matter entering and leaving the outer mantle of gray matter known as the cerebral cortex. Actually (1) the old cortex, seen in many lower animals as well as in man, seems primarily concerned with vegetative and emotional functions; (2) the new cortex subserves sensory motor, and associative functions. The new cortex may be subdivided into an occipital lobe in the back of the head, concerned with visual function; a temporal lobe on the lower side of the brain, concerned with auditory and language functions; a parietal lobe with the portion just behind the fissure of Rolando integrating sensory information coming from the skin and muscles; and a frontal lobe, with motor areas (just in front of the fissure of Rolando) controlling discrete movements and postural adjustments; the remainder of the frontal lobe is presumed to serve in complex associative functions, still poorly understood in the 1960s.

In this greatly simplified picture of the nervous system, sensory stimulation typically results in activation of integrative mechanisms at all levels, from the spinal cord to the cortex. The major sensory pathways described so far are quite discrete as to the sensory modality aroused and the part of the body or sensory surface stimulated; this gives the nervous system great discriminative powers. In addition, however, all the sensory pathways contribute branches to a feltwork of nerves lying in the centre of the hindbrain or brain stem (medulla and midbrain), known as the reticular formation. The reticular formation relays nerve impulses to all parts of the brain and serves the important function of activating or arousing the brain generally. It is believed that this arousal function is part of the mechanism of wakefulness, attention, and emotion, and thus it may be thought of as an important mechanism in the preparation of the brain for the reception of impulses arising from stimuli.

The great mass of the nervous system just described consists

FIG. 2.—SIDE VIEW OF HUMAN BRAIN, SHOWING MAJOR LOBES AND EXTERNAL SURFACE OF CORTEX

of billions of individual nerve cells, some of which send their tiny filaments all the way from the foot to the spinal cord, and some of which are not much longer than they are wide. These individual cells of the nervous system connect with each other across tiny gaps between them, known as synapses. Connections may be such that the activity in one cell will arouse activity in a number of connecting cells; or, conversely, activity in many cells may converge on a small number of cells; or there may be reverberatory loops such that a series of cells is activated in turn until the first cell is aroused again and again by the activity it initiated.

The activity of the nerve cells is detected as the nerve impulse, an electrochemical disturbance that may be propagated as rapidly as 120 m. per second. These disturbances can be recorded electrically with suitable amplification devices; such recording shows that if a nerve cell is to be activated at all, it must be stimulated by a certain minimal threshold energy; once a nerve cell is activated, it discharges fully.

Classically, two major integrative mechanisms have been described in the nervous system. One is excitation, the arousal of a nerve to activity; the other is inhibition, the effect of stopping activity in a group of cells. Excitation and inhibition can be illustrated in spinal reflexes, where painful stimulation leads to excitation of the nerves serving flexor muscles that pull the limb toward the body and to the simultaneous inhibition of the nerves leading to extensor muscles.

Sensation and Perception.—One of the oldest questions in physiological psychology is how information is received from the world outside the body and from within the body as well. For man, this is the problem of the anatomical and physiological basis of sensation and perception (*q.v.*).

An early concept concerning sensation and perception is the doctrine of specific nerve energies, first put forward by Johannes Peter Müller in 1826. While the anatomical and physiological details of this conception were inaccurate, the basic notion still seems valid. The doctrine states that sensations or responses to stimulation are determined by events in the nervous system. Thus a finger pressed on the closed eye mechanically produces visual experiences in the absence of the proper visual stimulus, light. Müller argued that people would see thunder and hear lightning if the nerves from the eye and the ear could be interchanged. Many phenomena support Müller's doctrine, but its general validity can be seen most easily in the fact that an electrical stimulus will produce experiences appropriate to the sensory system stimulated, whether it be the eye, the skin, the tongue, or some point within the brain to which impulses from these structures go. Thus the experience or the discriminative response is specifically related to the part of the nervous system that is activated.

To illustrate the point more fully, the case of hearing (*q.v.*) may be considered. The experience of pitch is determined largely by the vibration frequency of the sound source; the higher the frequency, the higher the pitch. Vibrations are transmitted through the air to the eardrum. The eardrum passes this vibration through tiny bones in the middle ear to vibrate the membrane of the oval window of the cochlea. This vibrates a fluid in the cochlea which, in turn, sets up a standing wave in the basilar mem-

brane, which extends throughout the coiled length of the cochlea. The standing wave has its maximum effect on the basilar membrane at different places, depending upon the frequency of vibration introduced. Low frequencies affect the basilar membrane near the apex of the cochlea, while higher frequencies have their effect near the base. The basilar membrane is lined with the hair cells of the organ of Corti, and as the membrane is moved, the shape of these hairs is distorted. Like crystals that are distorted mechanically, these hairs initiate tiny electrical currents, believed to stimulate the fibres of the auditory nerve that arise from the vicinity of the hairs. In this way, different fibres of the auditory nerve are activated by the different vibrations produced by tones of different frequencies.

More than that, the different auditory nerve fibres are kept distinct from each other in their course into the brain, at each of the relay stations, and at the auditory region of the temporal lobe of the cerebral cortex. Hence it is possible to record electrical activity along different parts of the auditory cortex, representing the different tonal frequencies that stimulate different parts of the basilar membrane. It is even possible (in a cat, for example) to stimulate different parts of the basilar membrane directly with electrical current and find the same array of different places activated in the cerebral cortex. So the experience of pitch seems to depend upon the place in the auditory nervous system that is activated by the stimulus.

The other attributes of sound are mediated by somewhat different mechanisms. Loudness depends on the intensity (*i.e.*, amplitude) of vibration, and it is believed that the experience of loudness is a function of the density of nerve impulses conducted over the nerve fibres serving the specific frequencies associated with pitch experience. Density can be increased by firing individual fibres more rapidly and by the activation of additional fibres of high threshold; *i.e.*, fibres that require a great deal of energy before they will fire.

The temporal pattern of pitches and loudnesses of sounds presumably is given by the temporal pattern of arousal of nerve fibres activated by a frequency- or intensity-patterned stimulus. Finally, the localization of sounds in space depends mainly upon the differences in time of arrival and intensity of vibration from a single source reaching the two ears. These differences show up in electrical recordings from the auditory cortex as appropriate differences in time of arrival and amplitude of nerve impulses on the two sides of the brain.

The same general principles apply to the other senses. Thus there are separate fibres and pathways in the spinal cord bearing nerve impulses produced by stimuli that give rise to experiences of pain, temperature, and pressure in the skin. Different parts of the tongue are activated by sweet, sour, bitter, and salty stimuli; as the tongue is stimulated more intensely, the density of the patterns of impulses increases proportionally. In vision, different parts of the receptor surface of the eye, the retina, are sensitive to the wavelengths of light that induce the experience of different colours. There appear to be different combinations of receptor cells in the retina that are maximally sensitive to different wavelengths in the visible spectrum. (*See also VISION; SMELL AND TASTE; TOUCH.*)

Physiological approaches to the more complex problems of perception can best be illustrated with some of the phenomena of vision such as the perception of real and apparent movement, the perception of depth, and visual localization. The visual localization of objects in space, for example, depends upon the part of the retina stimulated and the manner in which that localization is preserved in the brain. Philosophical interest in this problem arose when it was learned that the lens of the eye inverts the image of objects on the retina. The question then became: why do we not see the world upside down? This question inspired investigations into the role of early learning as related to the inversion of the visual field.

If the eye of a salamander is rotated 180°, the animal will snap upward at a lure held below it, and to the left at a lure held to its right. Even if the salamander's optic nerve is cut and allowed to grow back, the animal will not reorganize its vision in accordance

with its experience, and it will still be 180° out of phase upon recovery. The visual field of man also can be rotated experimentally with reversing lenses. Although there are individual differences, some people seem to adapt to such a visually reversed world, and after a time will say that things look upright again. Thus, although visual localization is largely a function of the central connections of the retina, it seems also to be modified by experience.

The role of the brain in perception has been studied in many animal experiments but is shown perhaps most clearly by the complex effects of brain injury on visual processes in man. In such cases, a man with damage to the area around the visual cortex may fail to recognize familiar objects for what they are (visual agnosia), although he may clearly be able to see them and describe their physical attributes. In other cases, such a brain-injured man may totally ignore all visual events occurring in some part of his visual field, although it can be shown by careful tests that he can actually see in that field; or in certain cases he may be subject to gross distortions in that visual field. Thus the brain, and particularly the cerebral cortex, is concerned with the interpretation of sensory impressions.

Motivated Behaviour and the Emotions.—A second problem of historic interest to physiological psychology concerns the basis of feelings, urges, and emotions—a most difficult area of scientific inquiry.

Behaviouristic analysis divides these complex behaviours into three components: (1) drive; (2) goal-directed behaviour; and (3) satiation. Drive (sometimes called instinct) is the arousal of the organism to intense activity, measured as an increase in general activity or the appearance of a highly specific activity. Thus the hungry animal becomes restless and hyperactive. Typically, however, the drive has a highly specific goal, such as food or a mate; or it might be a bodily expression as in the case of sleep or flight or rage. Upon execution of the behaviour, the organism tends to become satiated; drive is reduced, hyperactivity ceases, and behaviour is no longer directed strongly toward the goal. The clinical case of a three-year-old boy with a history of abnormal craving for salt illustrates the points of this analysis. This boy's history showed that his general appetite was poor and that he was restless and upset in his first years, when fed a normal diet. He strongly preferred salty foods such as bacon and crackers, and these seemed to appease him a great deal, but his great craving did not become apparent until he discovered the saltshaker at the age of 18 months and ate salt by the spoonful. Unfortunately, the case was not understood, and the child was belatedly taken to a hospital for observation and placed on a standard diet; within seven days he died. Autopsy revealed extensive damage to his adrenal glands, leading to a disorder in which the body cannot retain salt normally. Thus the boy had a deficiency which strongly drove him toward the specific goal of salt; when enough salt was ingested, the drive was reduced; it was thus, in repeated cycles of drive and satiation, that the boy managed to stay alive.

There may be two interrelated brain mechanisms, centring in the hypothalamus (*q.v.*): an excitatory mechanism for the arousal of drive and an inhibitory mechanism for its reduction or for satiation. For example, bilateral destruction of small areas in the ventromedial hypothalamus of the rat, cat, monkey, and possibly also man results in a doubling or tripling of food intake, leading to great obesity; on the other hand, similar destruction of nearby regions of the lateral hypothalamus, on either side of these first areas, results in refusal to eat and starvation in the presence of customary food supplies. That the first areas in the ventromedial hypothalamus are inhibitory is shown by another experiment in which electrodes, insulated except for their tips, are chronically implanted into this part of the brain. Electrical stimulation through these electrodes in the waking, hungry animal results in inhibition or depression of feeding. Conversely, the excitatory nature of the lateral areas is shown by the fact that electrical stimulation of these regions produces increased feeding.

Similar control mechanisms can be found in the hypothalamus in the cases of thirst, sexual behaviour, and sleep. In sexual behaviour it is clear that the hypothalamus also is directly influenced by sex hormones, for it is possible to arouse mating be-

haviour by introducing minute quantities of hormones directly into the brain through chronically implanted pipettes. The cerebral cortex also makes a contribution to the arousal of sexual behaviour, particularly in the male animal; extensive damage to the cortex may eliminate the possibility of sexual arousal. That the animal is still capable of mating, however, is quite clearly shown by the fact that a massive systemic dose of sex hormones can restore the mating response lost through decortication. Of further interest is the fact that sexual behaviour is independent of any particular sensory modality, including those arising from the genitals, for cutting the nerves from the genital area or surgical elimination of any one other sensory modality does not by itself affect sexual behaviour. In the naïve animal, it takes elimination of no more than two sensory avenues at once to preclude sexual arousal; in the experienced rat, however, sexual behaviour may survive the elimination of three modalities, illustrating the role of learning and experience in the physiological control of sexual behaviour. It is important to point out that the mechanism of sexual behaviour must have gone through marked changes in evolution. Comparing animals from rat to man, it is clear that there is a decreasing dependence on sex hormones and an increasing dependence on sensory stimuli, learning, and the cerebral cortex (*see* SEXUAL BEHAVIOUR).

Much the same physiological mechanism operates in the case of emotional expression. Cats deprived of the cerebral cortex are easily aroused to apparent rage by almost any mild stimulus, but their response is short-lived and poorly directed. If only the new cortex is removed, cats become placid; if the old cortex is removed alone, they become fierce. Monkeys, on the other hand, become strangely placid in the absence of certain portions of the old cortex, particularly the hippocampus and amygdala. These animals show, in addition to placidity, exaggerated sexuality and markedly increased and indiscriminate oral activity, even to the point of putting a snake or a lighted match into the mouth. Damage to different parts of the hypothalamus can also result in great changes in the expression of emotion. Electrical stimulation of the hypothalamus in people will lead to emotional responses such as weeping and laughter.

Electrical stimulation of the hypothalamus and related structures under somewhat different circumstances illustrates further the physiological mechanisms of motivation and emotion. In this case, an animal is allowed to press a lever which electrically stimulates its brain through chronically implanted electrodes. Such an animal will operate the lever as often as 5,000 times in one hour; under some conditions, pressing the lever is preferred to food, and it has been shown that animals will readily walk through a strongly electrified grid on repeated occasions to depress the lever. Such experiments demonstrate the rewarding nature of this stimulation and point to mechanisms that may mediate all positive emotion and motivation, including the experience called pleasure.

It may be concluded, in general, that the organism is aroused to strong motivated behaviour and emotion as a result of physiological activity in an excitatory neurological mechanism centring in the hypothalamus. Contributing to this are two major influences: (1) sensory stimuli, often as modified by learning; and (2) internal factors such as hormones, blood temperature, osmotic pressure, and salt levels. (*See also* EMOTION; INSTINCT; MOTIVATION.)

Learning and Intelligence.—While many remarkable adaptations are accomplished through instinct and motivated behaviour a major factor in the adaptation of the mammal, and especially of man, is the ability to learn. While the mechanism of learning (*q.v.*) is still poorly understood, learning and memory (*q.v.*) seem to depend on relatively enduring changes in the nervous system. Classically, two questions have been asked in this connection: (1) where in the nervous system is learning mediated? and (2) what is the nature of the underlying neurological changes?

There are many kinds of learning, but in all of them the organism makes a new response to some specific stimulus or to a general situation. Thus I. P. Pavlov's dog learned to salivate consistently in response to a bell, E. L. Thorndike's cats learned to press a

pedal that opened a door when they were locked in a cage and, as is known from common experience, the student of Latin-English vocabulary learns to say table when presented with *mensa*. Describing aspects of the process of learning and resultant memory are the so-called laws of association (see ASSOCIATION, MENTAL), some formulated by Aristotle, and others added through subsequent work: (1) contiguity in time and place; (2) repetition; (3) effect or reinforcement; and (4) interference, leading to forgetting or extinction.

Pavlov, for example, found it necessary to present the bell together with meat (a normal stimulus for salivation); this pairing had to be repeated many times before the bell alone would elicit salivation. The meat functioned as a reinforcement of learning in the sense that salivation to the bell lessened each time it was presented without the meat and increased each time the meat was included. The waning of salivation to the bell alone is called extinction and is similar to forgetting. Both extinction and forgetting appear to be the result of responses that interfere with the one that was learned; these interfering responses are favoured when reinforcement is omitted. There is reason to believe that most learning is permanent; most forgetting seems to result from masking by interfering or competitive learning. However, the commonly accepted notion that all experiences are stored permanently in the mind must be regarded with caution. There is growing evidence that specific memories may be permanently abolished through the selective destruction of brain tissue.

Many experiments have been directed toward answering the question of where learning is mediated in the nervous system. Pavlov believed that even simple learning such as conditioning depended upon the cerebral cortex, but it has been amply shown that animals may be conditioned after the cortex has been removed by experimental surgery. K. S. Lashley demonstrated, in a more complex learning situation, that rats surgically deprived of the visual cortex could learn to discriminate between a white square and a black square. But if an animal had learned this discrimination with the visual cortex intact, subsequent lesion of the visual cortex destroyed the discrimination; as would be expected, the discrimination could be relearned without the visual cortex about as rapidly as it was learned originally. This suggested that the memory for the discrimination was lost as a result of surgery but could be relearned with other parts of the brain. On the other hand, it might be that the memory was not lost, but rather that the animal was incapable of responding to the visual details of the black and white cards after operation and had to learn the problem without the benefit of detail vision; i.e., on the basis of ill-defined light and dark areas. That this may be so is suggested by the fact that the rat without its visual cortex cannot learn to discriminate a triangle from a circle where the difference in detail is the only basis for the discrimination. Conversely, if the animal is required to respond only to brightness change in a large area without any dependence on detail, it can retain a brightness discrimination without impairment after brain surgery.

Lashley also studied the role of the rat's cortex in maze learning and found that the larger the area of the cortex destroyed the poorer the learning and the poorer the retention of the maze learned before operation. It did not matter which parts of the cortex were destroyed and which remained intact, the result was the same: the larger the lesion, the greater the impairment. These findings led to the notions of mass action and equipotentiality, according to which maze learning is a function of the amount of cortex available and the various parts of the cortex are equally potential in subserving learning. Again it seems likely that these results can be understood in terms of sensory impairment. It is known from other studies that the more sense organs that are experimentally eliminated in the rat, the poorer the maze learning and retention; furthermore, no one sensory avenue is critical for such learning. Since the rat's cortex is mainly sensory in function, larger and larger cortical lesions would eliminate more and more sensory avenues centrally, and it may be for this reason that larger lesions impair learning and retention more than do smaller ones.

At one time it was thought that the frontal lobes of the brain

were critical in the memory processes demanded in the solution of difficult problems. Monkeys without their frontal lobes fail in the delayed reaction test, for example, where they are shown food placed under one of two identical cups and then made to wait for 10–60 seconds before being allowed to uncover the correct cup. Something other than memory is involved in this defect, however, for monkeys without frontal lobes turn out to be quite distractible. If their attention is fixed firmly on the baited cup before the delay, the lobectomized monkeys succeed; if the monkeys are made to keep very still by being put into darkness during the delay period or by being given sedatives, they also perform successfully.

The cortex therefore is important in the performance of a learned task, but probably more because of its importance in perception and attention than in learning per se. On the other hand, some of the difficulty in defining cortical function here may be due to the fact that these studies are based only on the method of experimentally damaging cortical tissue. When W. Penfield studied the temporal lobes of epileptic patients whose brains were exposed for surgery under local anesthesia, he found that electrical stimulation could evoke dreamlike sequences that contained familiar episodes from past life. Furthermore, when the temporal lobes are damaged in man, some curious memory defects do show up. While these patients are able to recall events from past life very well, they typically are unable to remember things they learned or experienced a few hours earlier. Closer examination shows that they actually do remember things they learn quite well if they are tested for memory within about 15 minutes, but beyond that the memory fades and is lost. It is as though there were two memory processes separated by the temporal lobe damage: (1) a temporary memory process capable of very short retention that is spared by the lesion; and (2) a more permanent memory process that is impaired by the lesion.

Support for this notion comes from several rather different experiments. In one performed on the octopus the animal was first presented with a crab, dangled in the far end of its tank, every two hours, six times a day. It quickly learned to venture out and eat the crab. Then, on half the tests, a white card was lowered with the crab, and with this cue the octopus learned not to venture out under penalty of electric shock. Thus a simple discrimination was learned. After removal of the vertical lobe of the brain, the octopus could no longer respond differentially in these tests; it kept emerging when the white card was presented. Even repeated trials every two hours with the white card and electric shock proved ineffective. But if the trials were run closer together, the octopus was able to perform much better; thus if a test came within 15 minutes to an hour after the octopus was shocked upon approaching the white card, it did not venture out toward the crab and white card. Again it appears as though the ability to carry a memory over a long period of time was impaired while very short-term memory was left intact.

In studies in which rats were given electroconvulsive shocks at some interval after each daily learning trial, additional evidence for a two-process memory was found. Here there was very little learning if the convulsive shocks were given within an hour after learning, but if the shocks came beyond an hour after each trial, learning was normal. Thus it seems to take some time for the effects of a learning trial to consolidate in the brain to a point of stability. For an hour after a learning experience, memory can be disrupted by convulsive shock, but after that it is not easily disturbed.

The conclusion from all these studies seems to be that the effects of learning are retained in the brain first by some reversible process, but that after some time (within an hour) some more permanent change takes place within the brain. It is suspected, therefore, that learning is mediated neurologically by at least two types of processes, and the time course of these processes is partly understood. It is still, however, possible only to speculate as to the nature of the change itself. It has been suggested that the first process, temporary and reversible, is a physiological process such as an electrical or chemical change at the synapse or perhaps at a group of synapses, so that a reverberatory loop is activated

for some period of time, keeping the memory trace alive. The second, more permanent process has been envisaged by some as an anatomical process consisting of the swelling of nerve terminals or the outgrowth of new terminals over short distances so that synapses are enriched in the number of anatomical contacts they have or that new synapses actually are formed. Another possibility, even more speculative, is that in learning there are changes in the chemical structure of nerves, possibly in the structure of complex protein molecules. Support for this kind of notion comes from the elucidation of mechanisms for coding genetic information in the structural arrangements of the large DNA molecule (see GENE). While there is no proof that learning and memory are coded in a similar fashion, the fact that memory in mice can be obliterated by intracranial injection of a drug (puromycin) that inhibits protein synthesis is highly suggestive.

As to the locus of the change that takes place in learning, there is still no certainty. Many studies show that the cerebral cortex is not essential for many kinds of learning, but they do not offer a positive clue as to where learning might take place outside the cortex. On the other hand, electrical recording studies report that electrical changes take place at many loci in the brain at once during learning. Whether some loci are more important than others, however, still is not known. (For a more detailed discussion of the processes of learning, see LEARNING; see also MEMORY.)

Related to the problem of learning are the even more complex problems of reasoning, problem solution, intelligence, and language. These have been studied primarily in cases of brain damage, particularly in man but to some extent also in animals. First, it should be pointed out that in both man and other animals large amounts of brain tissue may be destroyed without measurable impairment of these complex processes. For example, while removal of one entire cerebral hemisphere results in specific sensory and motor defects, intelligence within the sensory and motor capabilities of the person may be virtually unimpaired. On the other hand, lesions in certain restricted regions of the brain, particularly the cortex, may have devastating effects. Thus following damage in the dorsolateral surface of the frontal cerebral cortex, severe impairment, as measured by intelligence tests in man and tests such as delayed reaction in monkeys, may result. In man, there are also fairly specific speech areas in the lower parts of the sensory-motor area of the cortex in the dominant hemisphere. Damage here results in aphasia, in which there is an inability to name objects properly or to point to objects named by the examiner, even though in both cases the patient can see the object and say what it is used for (see SPEECH DISORDERS). If the lesion is at other temporal, parietal, or occipital loci, there may be difficulty in formulating language, in writing meaningfully (agraphia), or in comprehending written material (alexia).

As mentioned above, lesions in the visual association areas of the occipital lobe produce a visual agnosia in which familiar objects are not recognized even though elementary sensory processes are substantially normal. With parietal lobe lesions, there may be difficulty in recognition of parts of the environmental space, including one's own body, to produce what are called distortions of the body image. Often in such cases skilled acts such as putting on clothes cannot be carried out even though individual movements can be made normally, a disorder called apraxia. In some cases of frontal-lobe damage a patient may not be able to go through the motions of drinking from an empty glass, although he can easily drink from a glass with water in it when he is asked to do so. Disorders such as these are not well understood, but it is clear that in many instances relatively small lesions of the brain can lead to major psychological impairment.

Personality and Its Disorders.—For a long time the dominant thought has been that normal personality, neurosis, and psychosis are purely functional matters, the products of life experiences and life stress. But it has also long been held that personality is partly a matter of inherent physiological processes, some of which may be determined by heredity. Hippocrates, for example, believed that human temperament was largely determined by body fluids (humours). While his view was inaccurate in its details, there are nevertheless many examples in everyday life of the potent role

of body chemistry in personality; consider, for example, the effects of alcohol, mescaline (see PEYOTISM), opium, and nitrous oxide on human behaviour.

These drugs affect the functioning of the nervous system, and so also do many naturally occurring chemicals such as vitamins, hormones, and enzymes. Furthermore, the morphology of the nervous system and the enzymes directing its metabolism, and therefore its function, are functions of heredity. For example the striking case of feeble-mindedness known as phenylpyruvic oligophrenia is mediated by a defective gene that produces a defective enzyme. The resultant inability to metabolize phenylpyruvic acid in some way impairs brain function. F. J. Kallmann's studies of the major psychoses (q.v.) show that heredity is an important factor. When schizophrenia, for example, is diagnosed in one identical twin, it is very likely to occur in the other even if the two have been reared apart; fraternal twins, having no more similar heredity than siblings, show the same concordance as non-twin members of the same family, typically 10–15%. Quite clearly the genetic factor predisposes the individual to psychosis; life experience, stress, disease, or other factors may, of course, contribute to its precipitation. It is believed that the genetic predisposition is a biochemical defect affecting the nervous system, and the hope in the pharmacological treatment of psychiatric symptoms with tranquilizers and other inhibitors and exciters of brain chemistry is that the defect may be corrected or counteracted to some degree by drugs (see NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY).

Neuroses (q.v.) are much harder to understand than psychoses in physiological terms. Here genetic factors are less clear-cut, and the usual defect is not so severe and incapacitating as in the psychoses. The work of H. Selye and others, however, indicates that life stress and anxiety can have widespread correlates in the physiology of the organism, and it may be possible to understand neurosis as partly a matter of an altered physiological state. Experiments have shown that stress activates the pituitary gland, in part through the neurosecretory activity of the hypothalamus. The pituitary, in turn, releases hormones that activate other endocrine glands of the body, particularly the adrenal cortex. Once stressed, this system may become more sensitive to additional stresses, and two kinds of disorders may occur: an early one related to oversecretion of the adrenal gland and possibly contributing to such psychosomatic symptoms as hypertension; and a second one, due to adrenal exhaustion and perhaps contributing to symptoms of rheumatism and arthritis, also believed to be partly of psychosomatic origin. It appears that prolonged emotional stress may affect the physiology of the organism and sensitize it to further emotional disturbances.

PSYCHOLOGY, SOCIAL. Social psychology is the study of individual activity as related to social factors. Although social psychologists may be interested in such topics as the dominance of chickens in pecking one another (see SOCIOLOGY, ANIMAL), or in the dance some bees use to communicate the location of a patch of clover to others in the hive (see SOCIAL INSECTS), human social behaviour has received the bulk of attention. Clearly, the concerns of social psychology have much in common with those of psychology, sociology and social anthropology (qq.v.); and applications are to be found in such aspects of daily life as politics, religion, economics and mental health.

By the 1960s social psychology had produced an impressively

diverse set of empirical findings somewhat loosely bound by ill-fitting patches of theory. In the 19th and early 20th centuries the situation was almost the reverse; there was virtually no experimentation and little careful collection of objective data. It was a period of extremely general theories that have been characterized by G. W. Allport (*q.v.*) as simple sovereign theories. By and large they arose in social philosophy and continually were being modified under the impetus of developments in economics, physical and biological sciences, anthropology, political science and psychoanalysis. This uneasy movement in response to intellectual fashions made it clear that social psychology lacked a solid scientific foundation.

This state of affairs in social psychology was interrupted about 1920 when human instinct theory fell into disfavour. It was at this time that social psychologists seemed to recognize that the search for a touchstone theory, as simple as parts of classical physics, had failed. The wide variety of empirical studies that followed ushered in modern social psychology. Between 1925 and 1945, such research techniques and devices as sociometry, audience reaction measurement, inexpensive recordings for the study of face-to-face interaction, the use of role players as social stimuli, and new modes of attitude assessment made social behaviour more accessible to first-hand study and revealed the value of working with simpler, more readily soluble problems. These new techniques found many applications in World War II and the skills developed in military investigations were subsequently widely applied in U.S., British and Scandinavian universities. These developments are elaborated below. With studies of new problems and smaller segments of earlier problems, there was, however, a growing sense that the complexity of social behaviour may continue to resist synthesis and require the development of many specialities within social psychology.

Early Problems of Social Psychology.—A classic simple sovereign theory involved the psychological hedonism of Jeremy Bentham (1748–1832), who reduced human motives to seeking pleasure and avoiding pain. It was assumed that more stable aspects of human personality were calculated to bring maximum, long-term pleasure to the individual. The same theory had been expressed earlier by Epicurus, Thomas Hobbes and many others; but Bentham elaborated and carefully described different attributes of pleasure and pain. Typical of social theorists, Bentham went beyond pure science, offering his notions in a widely debated ethical theory of utilitarianism (*q.v.*). Herbert Spencer (1820–1903) accepted Bentham's formulations and incorporated into his notions of evolution the idea that organisms most successful in the avoidance of pain survive best.

Later, in an effort to account for such behaviour as seen in trends of fashion, dancing manias and health fads, the term suggestion came into use, particularly for situations in which people accept propositions without logical support. In the writings of J. M. Baldwin (1861–1934) imitation and suggestion were offered as essential processes in early socialization. These nonrationalistic mechanisms were held necessary to start the social process, but were considered something to be outgrown. Writers like G. Le Bon (1841–1931) and S. Sighele (1868–1913) found much evil in these mechanisms. They held man to be unconsciously bestial and criminal; crowds, therefore, were seen as menaces to established institutions: "crowds flourish as civilizations decline." Sighele anticipated later developments by considering two-person (dyadic) relations where one makes suggestions and the other responds without being normally critical. H. Bernheim's (1837–1919) work in hypnosis (*q.v.*) led him into a controversy with J. M. Charcot (1825–93), who taught that only people with hysteria (*q.v.*) could be hypnotized. While time has given more support to Bernheim's position that there is no such discontinuity between normal and abnormal suggestibility, this controversy between French psychiatrists was notable as a historical accident that brought social and abnormal psychology closer together.

William McDougall, in his *Introduction to Social Psychology* (1908), assumed that directly or indirectly men are moved "by a variety of impulses whose nature has been determined through long ages of evolutionary process." For McDougall the fundamental

problem of social psychology was to explain how people become moral and co-operative members of society. In this McDougall anticipated the modern interest of social psychology in the socialization of children. His biological standpoint led him to offer a system of instincts, innate psychophysical dispositions to perceive objects and experience emotions, that lead to action. He posited 13 instincts, including the parental or protective, the instincts of combat, curiosity and gregariousness (in turn built on 6 minor instincts involved with vegetative functions of the body). McDougall's notions became popular objects of derision during the 1920s; but by 1949 G. Murphy was writing "with the passage of the intense wave of anti-McDougall feeling, instinctive mechanisms have come slowly back into place."

Behaviourism (*q.v.*) contributed the theory that human genetic endowments (prepotent reflexes and primary drives) were conditioned into chains of acquired habits seen in mature social behaviour. The position that human nature depends on environmental rewards and thus is alterable, was attractive to many and tended to increase experimentation. Social psychologists familiar with psychological traditions—first in Europe, then in the U.S.—became the important experimenters. In contrast, those recruited from a background of sociological tradition tended to avoid experiment and to concentrate on psychological processes in field situations and institutional contexts.

Simple Group Effects.—Early studies by N. Triplett (1897) showed that people tended to accomplish more in such tasks as spool winding when working in groups than when they worked alone. At first the work increment was attributed to the presence of someone to set the pace. However, later research revealed that the group effect could be produced even if others were not present, provided the subjects believed they were members of groups. This modest research helped to popularize group experimentation and indicated that behaviour may be modified through a desire to conform to what are believed to be group norms.

A classic experiment that followed illustrated that membership in a group can influence the way an individual perceives. In the dark, with no background visible as a frame of reference, a stationary pinpoint of light appears to move. Called the autokinetic effect, this illusion is experienced as movement over distances that vary considerably from observer to observer. M. Sherif demonstrated that people tend to perceive these distances closer to the group average when they report their experiences to each other. He also found that, if initial exposure is in a group, individuals later tend to abide by the group norm when they observe alone. Generally this has been taken to mean that people depend heavily on judgments of others when objective standards are lacking.

Similarly it has been observed that in fashions, attitudes toward racial or religious groups, and similar social behaviour, individuals are apt to respond alone as they have learned to do as members of groups. For example, with individual interviews, Conrad Chyatte, M. Spiaggia and D. Schaefer (1951) found white, non-Jewish children were more likely to verbalize prejudice against Negroes and Jews in Virginia and North Carolina than in New York city. Systematic differences related to the national origin of the child's family were also observed—further evidence that prejudice involves group conformity.

It has been demonstrated that group effects are not limited to subjective judgments. To illustrate this S. E. Asch instructed 11 confederates to report the distinguishably shortest of two lines as being longest. Many individuals, serving as 12th member of the panel, found it difficult to resist the social pressure and give the correct response. However, if even one other group member gave the correct judgment, the effect of the remaining 10 was greatly lessened. This finding has clear implications in the study of decision making by such groups as juries and planning boards.

Such studies, whether in laboratories or in the contexts of society, touch on the individual's search for validation in the responses of others. As one verifies with his own senses what others have told him, he gains confidence in their reports about external objects. He also needs to test his perceptions of himself as a social object. It is interesting that this more difficult subject was thoroughly discussed in the literature of social psychology before

the formation of attitudes toward objects other than the self was very extensively analyzed.

The Self and the Primary Group.—G. H. Mead (1922) described personality formation without positing inherited social instincts. In his description the self emerged when the individual perceived himself as a social object. The growing child was seen as duplicating the reactions of others toward him in a process Mead called role-taking.

Roles were described as being highly specific at the outset. For example, a child may assume parental speech and actions toward his toys and real or imaginary playmates, and in fantasy may play many roles. The child talks to himself as he has heard others talk (see CHILD PSYCHOLOGY; PERSONALITY).

Yet roles do not remain entirely specific. The repetition of similar drives and situations leads to more general roles. An early general role molded by the individual's status and function in the family is later modified in other primary associations. C. H. Cooley, in *Social Organization* (1909), maintained that primary groups ("characterized by intimate face to face association and cooperation") not only give an individual his earliest experiences of social unity but they form a recurrent source of new relationships. For primary groups to fulfill these functions he anticipated that systematic differentiation in roles must arise and modes of social control must necessarily be created. Cooley's writings stressed that notwithstanding the physical discreteness of individuals, and although the raw material out of which group activity develops is to be found in the activities of individuals, these individual activities are, in a very definite sense, group products.

Communication and Attitude Change.—Attitude and opinion may be technically distinguished: the tendency of an individual to evaluate anything favourably or unfavourably is an attitude, whereas an opinion has sometimes been defined as an overt verbal evaluation. In these terms opinions need not correspond to attitudes, and attitudes may be expressed by actions other than verbal behaviour. Verbal opinion is thus a fallible predictor of action (see ATTITUDE).

One of the simpler techniques for changing opinion is to call attention to the individual's group membership; this is intended to prompt people to take group norms into account in response to persuasive communication. Experimentally, communications attributed to sources of low credibility are perceived as biased and unfair while the identical communications, when attributed to more trusted sources, tend to be significantly more persuasive. While these effects tend to disappear after several weeks under the limited conditions of such experiments, they are of great importance in daily life (C. I. Hovland *et al.*, 1951, 1953).

Other studies indicate that, in dealing with hard-to-understand issues, greatest opinion change is effected when the persuader offers a definite conclusion. In more familiar areas, where there is less dependence on experts, it is probably more effective to leave the conclusion to be drawn by the hearer. When alternate sides of a question are presented in such experiments, opinions formed tend to resist change in the face of subsequent efforts (H. C. Kelman, C. I. Hovland, 1952, 1953).

Arguments associated with mistrusted sources sometimes have greater effects in these studies after a lapse in time. This has been interpreted to mean that people tend to forget the association between argument and source and become freer to make evaluations on merit. A most interesting finding from communication research indicates that, if appeals based on fear arouse strong tensions that the persuasive communication fails to relieve, people tend to minimize the threat and to disregard the communication. Fear appeals producing milder tensions are much more effective in motivating experimental subjects to action.

Persons highly motivated to retain membership in a group tend to resist even logical arguments that contradict the norms of the group. Individual response to persuasion is theorized to be a function of the attention given the communication, the comprehension of the message, and the individual's ability to anticipate the relevance of communicated incentives to his own needs. Persuasion is held to become more difficult as the person attempts to

appraise the validity of the argument and evaluate the communicator's motives. A most effective experimental technique for changing opinion is to persuade the subject to play the role of an experimenter seeking to persuade others. If his attempts are successful, his own opinions substantially tend to change.

Many aspects of attitude change can be subsumed under a theory popularized by L. Festinger (1957, 1962). Essentially the theory offers the notion that, when faced with discrepancies in what they perceive (cognitive dissonance), people tend to reduce such inconsistencies by shifts in attitude. For example, consider the case of a politically conservative student who discovers an admired teacher to be politically radical. From the theory it would be predicted that in restoring balance to his cognitive field the student either will tend to become less conservative or lose admiration for the teacher.

The same factors seem to operate after difficult choices are made. Suppose a man buys an automobile after considerable debate about the highly attractive merits of another brand. It has been found that such a person will tend to read with renewed interest the advertising that describes the good points of the vehicle he has bought, apparently tending to overcome the cognitive dissonance generated by the tempting brand he failed to buy (D. Ehrlich *et al.*, 1957).

In other experiments opinions about doing unpleasant tasks were found to become less favourable as the reward for the work became increasingly high; and more favourable with relatively modest reward. This apparently paradoxical finding has been interpreted as meaning that high reward is perceived as an adequate reason for doing the work, while modest reward creates cognitive imbalance that is compensated by positive change in attitude. This line of analysis has led to the suggestion that people will tend to be most happy in a job if the rewards are just enough to motivate them to work (L. Festinger and J. Carlsmith, 1959).

One of the most challenging areas of social psychology involves attitudes based on motives that would be unacceptable to an individual if they were consciously expressed. The work of T. W. Adorno *et al.* (1950) has approached the problem, relying heavily on the theories of psychoanalysis (*q.v.*). These authors argue that the authoritarian personality (a person who defers excessively toward strength and status and is aggressive toward weaker people) unconsciously harbours aggressive motives toward his parents (see DEFENSE MECHANISMS). To cope with such consciously unacceptable feelings the authoritarian personality is held to develop an uncritically favourable attitude toward his parents (reaction formation); to attribute the unacceptable hostility to others (projection); and to redirect the aggression toward weaker persons (displacement). Although it was particularly concerned with explaining the psychological basis of anti-Semitism, the work has been widely cited with regard to other instances of prejudice and hostility.

Socialization and Value Systems.—In considering the development of social behaviour, various cultures have been studied in order to compare the effects of different child-rearing practices. It has been found that practices dealing with feeding, toilet training, dependency, sex and aggressiveness do not appear to be highly correlated. Most of the data obtained thus far do little more than to relate specific ways of treating children to specific larger aspects of particular societies. For example, the practice of feeding infants whenever they are hungry tends to characterize cultures with co-operative economies, and strictly scheduled feeding is used to a greater extent in cultures with competitive economies. These instances must, however, be considered as hypotheses to be validated in other ways, but the case for the interplay between attitudes toward social institutions and child training is becoming increasingly convincing (J. Whiting and I. Child, 1953; Y. A. Cohen, 1953).

It is not clear whether the social institution shapes infancy training or whether the training induces needs that are expressed in institutional and cultural forms. For example, it is believed that funeral ceremonies often have the function of permitting people who may have both loved and hated the deceased to obtain public recognition that they experience sorrow and thereby reduce

feelings of guilt. This is a simple instance of a need that may be associated with institutional practice. It is in the explanations of such behaviour that social psychology bridges sociology and social anthropology. One report (J. M. Whiting *et al.*, 1958) indicates that almost all societies with exclusive mother-son sleeping arrangements for the first year of the son's life (during which the mother is prohibited from sexual intercourse) have one of two patterns of behaviour. Either there is a ceremony of initiation into manhood involving such activities as hazing by adult males, acts of endurance and manliness, seclusion from women and painful genital operations, or there is a change of residence that separates the boy from his mother and sisters, commonly placing him under the guidance of an uncle or other males in the community. These measures were interpreted as efforts to overcome emotional dependency, incestuous feelings and hostility toward the father, all held to arise from the practice of sleeping with the mother.

Such inquiries seem remote from the concerns of modern society, but similar ideas have been offered to explain the fact that broken homes are associated with increased delinquency among boys in urban centres. It has been predicted that delinquency will be most likely when the separation of the parents occurs in the child's early infancy, and that a change of residence along with an initiation ceremony and exposure to the authority of responsible adult males may serve to reduce delinquent behaviour.

It is known that people with low social rank doubt the ability of their group to accomplish its goals and are least apt to conform to its norms. D. McClelland *et al.* (1958) have indicated that where the father dominates in reconciling differences among family members, the adolescent son tends to be reluctant to leave home to strike out on his own and prefers to work in groups rather than assume individual responsibility. Thus, the structure of the primary group, as well as that of the larger society, may be expected to contribute to the shaping of attitudes.

Interacting Groups and Reference Groups.—G. C. Homans (1950), on the basis of studies ranging through primitive people, street-corner gangs and industrial settings, offered such generalizations as: (1) the more frequently persons mutually interact the stronger their friendship is apt to be; (2) the higher a person's rank in a group the more he talks and is talked to; (3) people who talk together frequently resemble each other more in their activities than do persons with whom they talk less frequently; (4) people are more likely to talk together if their social ranks are closer; (5) conformity to group norms increases the degree to which an individual is liked by others in the group; and (6) the closer one comes to realizing the norms of his group, the more he is talked to by others, the higher his rank and the more his behaviour is like that of a leader.

Homans' principles illustrate relationships that tend to hold over a wide range of human group situations. Later investigation showed that when a departure from group norms is essential to the successful adaptation of a group, then the higher-ranking, more secure members of the group are the ones most likely to act at variance to earlier norms. It is to be hoped that such formulations may be incorporated into a more general theory.

The speed with which regularities in group behaviour were being discovered increased greatly after the end of World War II, largely because of the spread of skills required to manage small groups. For example, an experimenter who wishes to increase the cohesiveness of a two-person group may simply tell the pair that they have been selected because they are known to have traits of people likely to be congenial with one another. In contrast with control groups that do not receive these instructions, it has been found that such instructed pairs co-operate much more readily in experiments. Comparable effects may be obtained by telling subjects they are particularly well fitted to do the job together or particularly likely to appreciate the value of belonging to the group (K. Back, 1951). Such experiments demonstrate that cohesiveness (the attractiveness of a group to its members) can be implemented by verbal instructions.

In the analysis of conformity, T. M. Newcomb (1943) studied students from conservative family (reference group) backgrounds at a politically liberal girls' college. He found that those who

sought and obtained acceptance and higher rank changed their political attitudes in a liberal direction between their freshman and senior years. Girls who were well accepted despite being conservative were described as active and enthusiastic (presumably in nonpolitical school activities) and tended to refer attitudes toward public issues to their home and family groups. In some cases girls who remained conservative either made the social attitudes of the school a target of negative reference or were found to be docile and much less active.

Considerably greater coercive pressure is brought to bear in brainwashing (*q.v.*) as suffered by prisoners of war. Captors segregate potential leaders, deny informational support by means of censorship, create distrust by suggesting the presence of informers, withdraw group privileges because of resistance by one person, publicize any collaboration, place demands for conformity so slowly that logically resistance seems unwarranted, maintain deprivation and then give small rewards for conforming. Behind this is the continued threat of physical harm and nonrepatriation.

Investigators also have conducted experiments outside of the laboratory. Boys in cabins at summer camp were made hostile to groups in other cabins as a result of successive competitive activities. It was possible to eliminate the hostility by assigning tasks requiring co-operation among the groups.

Experimental studies of group interaction, the scaling of social attitudes and the highly technical sampling decisions involved in the design of public-opinion surveys require advanced statistical methods. Such techniques are required in other aspects of psychology, social anthropology and sociology; and statistical training was a part of most such programs in British and U.S. universities by the 1960s. However, one demanding skill frequently required of social psychologists for use in the study of group interaction is the scoring of the successive (and sometimes simultaneous) verbalizations of group members. One of the best-known systems (R. F. Bales, 1950) breaks the interaction into units (acts) roughly equivalent to simple declarative sentences and identifies the originator and target of the act. Use of the technique has shown that, as group size increases, the most vocal participant increasingly tends to exceed his pro-rata share of the available time. Dissatisfaction of other group members seeking to be heard may be relieved by such measures as reducing group size and the assignment of roles designed to reduce power and status differences.

Investigators may use interacting groups as analogues for such complicated social situations as those involving the creation of inventions under differing degrees of cultural contact or the behaviour of parties in international political affairs. A. Mintz (1951) applies this approach in making inferences about mobs in panic. His findings cast doubt on the theory that extreme emotional threat is essential for panic at theatre fires and similar crises by showing that groups faced with a task as simple as pulling pegs out of a small-necked bottle will panic (*i.e.*, jam the pegs) when individual rewards for being "first out" are offered. Such exercises suggest that panic arises from a recognition that other group members are quite unlikely to co-operate as required. The attendant emotionality thus may be considered a response to the breakdown in behaviour of fellow members rather than to the intensity of threat.

Collective Behaviour.—Behaviour generally related to panic includes the phenomena of lynchings and riots, and acquisitive jostling and excitement at bargain sales or in anticipation of rationing and shortages. Clearly there is an emergent quality to collective behaviour; people are changed by seeing many others intent on a goal, and there is a loss of some degree of self-consciousness. Tricks of memory and distortions in message reproduction, as they apply to bits of rumour circulated prior to various collective actions, are examples of other psychological processes involved.

Behind the transmission of rumour, for example, is the question of what a person will perceive, remember and tell others. By having experimental subjects recall, after a lapse of time, a dramatic but exotic folktale, it may be shown that these people shorten the story, mainly by omissions; the phraseology becomes more journalistic; and, if the original story was somewhat incoherent,

it becomes more coherent. When the story is transmitted along a chain of people (serial reproduction), as much leveling of detail occurs in a few minutes as individual memory accomplishes in weeks. With more realistic stories retelling tends to increase number, size or cost; makes old events more recent; retains and accentuates implications of movement; and tends to add explanations. Once the principal theme has been understood the hearer condenses and changes the story to conform to reality as he understands it. For example, in one study (G. W. Allport and L. J. Postman, 1947), white observers were shown a picture of a Negro standing near a white person who was holding a razor. Half of the serial reproductions initiated after showing the picture resulted in reports that the razor was in the Negro's hand; in some cases the Negro was said to be brandishing the razor or threatening the white man.

In summary, stimuli subject to divergent interpretations initiate a subjective search (by means of leveling of detail, sharpening and assimilation to theme) to reduce the stimulus to a simple structure that is meaningful in the individual's own experience. The more people involved in a serial report, the greater the change is likely to be until the rumour has reached aphoristic brevity and is repeated by rote. In short, topical propositions for belief without supporting evidence (rumours) can be shown to be systematically defective as guides for either belief or action, even though they may fulfill important expressive needs of the persons who transmit and receive them.

The mention of lynching and rumour stresses the ominous side of collective behaviour; but, change in women's fashions is just as properly a collective phenomenon. There is some evidence in contemporary western society for the notion that dress styles percolate down from higher to lower social strata. It is also generally believed that advertising provides a necessary exposure to the new ideas, that salespersons and others seen wearing the styles make a contributory addition, but that in the final analysis information is not enough. People commonly wait for approval of the style change by respected and trusted associates. Thus, advertising informs, but opinion leaders in the local network of interpersonal influence give legitimacy to the innovations.

Greater urgency has been added to the study of consumer decisions by a growing concern over resistance in adopting new products and methods in underdeveloped countries, especially in agriculture in connection with the use of hybrid corn, improved feeds and so on. From an earlier position in which interpersonal relations were viewed simply as intervening in the communication process, social psychology has advanced toward greater specification of the important role they play. For example, it has been found that U.S. physicians in the same local social cliques tend to make their first prescriptions of a new drug at about the same time, and that among these cliques the opinion leaders are characterized by more frequent attendance at medical society meetings as well as broad contacts within their clique. While physicians more isolated from colleagues depend on sales representatives from drug manufacturers, journal reports on drugs are still legitimated in an interpersonal network before they are acted upon (H. Menzel and E. Katz, 1955).

In the great popular fads of the Yo-yo, bobbed hair and the hula hoop, adolescents have been identified as having a conspicuous role as agents of change. And, as the history of bobbed hair well attests, all fads do not have necessarily the steeply rising, quickly falling popularity associated with the great majority; many become relatively permanent parts of the culture.

In the study of the behaviour of audiences listening to speakers, the loss of self-consciousness that attends growing identification with the speaker has been found to involve some of the same structuring tendencies found in rumour studies. Thus, if incongruous elements are introduced into the speaker's message, these are relatively unlikely to be remembered.

Control of group behaviour is frequently attempted through the use of collective images or stereotypes. Antireligious activities, for example, may foster the collective image of a greedy, hypocritical clergy. Pharmaceutical manufacturers, in responding to charges of excess profit-taking coupled with publicity given to

drugs that produce birth deformities, spend considerable sums in an attempt to bolster the collective image of their industry. Mothers, including those who are unworthy, bask in the image of a benign, altruistic collective mother. Collective images can have great influence on the public acceptance of ideas, depending on whether the ideas are associated with trusted or mistrusted images. Control of mass-communication media that foster and perpetuate so many collective images thus looms enormously important in molding public attitudes. However, such efforts may have unanticipated results. For example, if, in a country with commercial television, businessmen compete by praising their own products and politicians compete by denouncing the opposition, the result may be perceived as unopposed praise for business and slander for politics. This may well shape the attractiveness of business and politics as careers.

There is, in the literature on collective behaviour, at least one well-documented instance of a radio audience being moved to panic. *The Invasion From Mars* (1940) by H. Cantril, H. Gaudet and H. Hertzog analyzed the response of thousands of people in the U.S. to a fictional radio drama that realistically described a meteorite supposed to have landed in New Jersey. "It was surrounded by a green gas," "it was not a meteorite but a metal casing," "the top began to unscrew," and the invasion from Mars was on. Listeners who waited for reassurance from the announcer were surprised to hear his voice rising in tremendous emotion as he moved from "This is terrific," to "This is the most terrifying thing I ever witnessed." Throughout the country thousands of people prayed, telephoned warnings, woke children, drove at dangerous speeds or prepared to flee.

There were undoubtedly situational factors that contributed to the panic. The U.S. was still in a prolonged economic depression and other broadcasts had been interrupted to present legitimate war news—the date of the broadcast was Oct. 30, 1938. Most knew very little about what might be expected from Mars, and most had an unchallenged confidence in what they heard over their radios. Some listeners who attended to evidence given in the broadcast (particularly the speed with which purported scientists and high government officials were contacted) recognized that they were hearing an extremely good piece of fiction. Others, who listened less fully, turned to neighbours who either commonly were uninformed or similarly were in search of confirmation. This added to the anxiety, and frightened listeners continued to take increasingly desperate steps before they met convincing reassurance. However, by midnight of the evening of the broadcast the panic had virtually passed. But thousands had seen in their own reactions the human disposition to turn to the immediate welfare of self and family when faced by incalculable threat.

PSYCHOPHYSICAL METHODS. Psychophysics is the science concerned with quantitative relations between psychological events and physical events or, more specifically, with quantitative relations between sensations and the stimuli that produce them. Psychophysical methods are those methods developed for the purpose of specifying and testing such quantitative relations.

Physical science enables us, at least for some of the senses, to measure with accuracy on a physical scale the magnitude of a stimulus. By determining that stimulus magnitude just sufficient to produce a sensation (or a response), it is possible to specify the minimum sensible stimulus or the absolute stimulus threshold (stimulus limen) for the various senses. It is also possible, although practically more difficult, to determine the lowest stimulus magnitude that produces maximal sensation, the terminal threshold; i.e., that point on the physical scale beyond which no increase in stimulus produces any appreciable increase in sensation. Thus are determined limiting stimulus values, between which changes in stimulus intensity are accompanied by changes in sensation. The central inquiry of psychophysics pertains to the search for a lawful quantitative relation between stimulus and sensation for the range of stimuli between these limits (see SENSATION).

Psychophysics was established by Gustav Theodor Fechner (q.v.), who coined the word, invented the three fundamental methods, conducted elaborate psychophysical experiments and began a line of investigation that still persists in experimental psychology. Fechner's classic book, *Die Elemente der Psychophysik* (1860), may be looked upon as the beginning not only of psychophysics but also of experimental psychology (see PSYCHOLOGY, EXPERIMENTAL). Fechner, trained in physics, became interested in his later life in metaphysics and cast about for a way of relating the spiritual to the physical world. He hit upon the notion of measuring sensation in relation to its stimulus. The physiologist Ernst Heinrich Weber (q.v.) had discovered that the amount of change in magnitude of a given stimulus necessary to produce a just noticeable change in sensation always bore an approximately constant ratio to the total stimulus magnitude. This fact, properly speaking, is Weber's law: if two weights differ by a just noticeable amount when separated by a given increment, then, when the weights are increased, the increment must be proportionally increased for the difference to remain just noticeable. Fechner chanced upon Weber's law and undertook to use it for the measurement of sensation. If R be the stimulus (*Reiz*), and S be the resultant sensation, and Δ signify an increment of either, then Weber's law becomes $\Delta R/R = a$ constant, for the just noticeable difference. Fechner went further and assumed that all equal increments of sensation must be proportional to the same ratio, $\Delta R/R$, that is to say, $\Delta S = c \Delta R/R$, where c is a constant of proportionality. If this equation is integrated, if R be assigned a value of zero corresponding to the absolute stimulus threshold and if the constant be changed to k for common logarithms, the result is $S = k \log R$.

This particular formula Fechner named Weber's law, although it is really Fechner's law and is thus often called the Fechner-Weber law. It expresses the simple relation that the magnitude of a stimulus must be increased geometrically if the magnitude of sensation is to increase arithmetically. For Fechner it meant that the relation between the spiritual and physical worlds is stable and that there is therefore only one world, the spiritual; but for physiologists and for many philosophers it meant the

measuring of sensation in relation to a measured stimulus and thus the possibility of a scientific quantitative psychology. Fechner got his conception of psychological measurement from J. F. Herbart (q.v.), but he was really refuting Herbart in demonstrating that psychology can be experimental.

Fechner's original work stimulated much research and much controversy. It was argued against him that it is introspectively obvious that sensations do not have magnitude (the quantity objection), that "a scarlet is not just so many pinks." This difficulty was met by the Belgian J. R. L. Delboeuf (1831-96), who developed the concept of the sense-distance, holding that sensations, although not complex magnitudes, are separated by variable intervals that can be compared as being greater, equal or less, one to another. In Germany Georg Elias Müller (1850-1934) undertook an elaborate criticism of Fechner and an extension of his work. In the United States E. B. Titchener (q.v.) made a historical and practical exposition of psychophysics in the second volume of his *Experimental Psychology* (1905). F. M. Urban, then also in the U.S., improved one of the methods and developed the concept of the psychometric curve or psychometric function. In England William Brown (1881-1952) and Sir Godfrey Thomson (1881-1955) were prominent psychophysicists.

Three Classical Psychophysical Methods.—Among the lasting contributions of Fechner are the three fundamental psychophysical methods he invented. Each method is designed to investigate the nature of relationship between the psychological scale and the physical stimulus scale.

Method of Minimal Changes.—This, also called the method of limits or of just noticeable differences, consists of successively adding small constant increments of intensity to a stimulus until a change is noticed. For example, to determine the absolute stimulus threshold of intensity, imperceptible intensities are presented in increasing order until the stimulus is first sensed; then a descending series from perceptible to imperceptible is observed. The results of many such series are averaged to determine a single reliable estimate of threshold value. To find the difference limen or difference threshold (the difference between two stimuli that marks the boundary between sensed difference and sensed equality) two stimuli always are presented. One, the standard stimulus, is kept constant while the other, the variable, is successively altered by small amounts until a difference between the variable and the standard appears or disappears, according to the direction of change. The difference threshold is the distance from the standard to the average point of change, and there are always both an upper and a lower difference threshold, since change can be noticed on either side of the standard. The method of minimal changes has been used primarily to find intensity thresholds for sounds, odours, tastes, colours, temperature, pain, brightness and tactual stimuli, to name a few.

Method of Average Error.—The method of average error, or method of reproduction, also makes use of two stimuli, a variable and a standard, but in this case the variable is capable of continuous change (in intensity, say) by the turn of a dial. The task of the experimental subject is to adjust the variable stimulus until it is subjectively equal to the standard stimulus. Since subjective equality is not physical equality, the results yield an average error (from physical equality), constant for the subject, and also a variable error about his average. The method of average error has been applied most frequently to the study of visual distance, particularly to determine extent of visual illusions.

Constant Method.—In the constant method the subject is presented, in random order, a predetermined set of stimuli, for each of which he judges presence or absence of a sensation. In the typical application of the method, each selected stimulus is presented a large number of times. As an example from the cutaneous field, consider determination of the two-point tactual threshold. With an esthesiometer two points at graduated distances are simultaneously stimulated on the skin. The subject's task is to distinguish between two points and one. Depending upon the part of the body stimulated, the two-point threshold may vary from approximately 1 mm. (tip of the tongue) to about

70 mm. (parts of the back, thigh, and upper arm). On the basis of preliminary trials, six or seven distinct distances (stimuli) might be selected so as to include the threshold for a particular subject and a given part of the body. By presenting each stimulus 100 times, a stable estimate for two-point threshold could be obtained. (Due to variability in the conditions of excitation, repeated application of the same stimulus distance is not expected always to yield the same judgment from the subject. However, as the two-point distance increases, the frequency with which the difference is reported increases. The value of that stimulus distance resulting in an equal number of judgments of one point and of two points can be taken as the threshold.)

In a somewhat different application of the constant method, two distinct stimuli are presented, either simultaneously or successively, and the subject is instructed to judge whether stimulus *B* is greater than, equal to, or less than stimulus *A*. Stimulus *A* might be a standard stimulus, presented on each trial; the second stimulus might have any one of six or seven preselected values.

A classic example is that of lifted weights: on each trial a standard weight is compared with a variable weight, and the subject responds with one of three possible judgments. Values for the variable stimulus are selected, some to be heavier and some to be lighter than the standard. Each value of the variable stimulus might be presented with the standard 100 or more times, with order of presentation randomized. Relative frequencies of judgments may be plotted as shown (see diagram). It may be seen that as the variable stimulus becomes heavier the frequency with which the variable is judged as less than the standard decreases, the frequency of greater judgments increases, while the judgments of equality become first more, then less frequent, with a maximum near the centre. The lower threshold or limen value L_l of the stimulus is taken as that value where the judgment of less is as likely as it is not; i.e., that point on the stimulus scale corresponding to 50% judgment of less. The upper liminal stimulus L_u is similarly defined, with reference to the distribution of greater judgments (sometimes called the psychometric function for greater judgments). The difference limens are the distances of these liminal values from the standard stimulus *S* (the distances L_l to *S* and L_u to *S*). Subjective equality of variable to standard stimulus is usually taken as the point where judgments of less and greater are equally likely; i.e., where the two psychometric functions intersect. Empirically it has been found for a wide range of situations that the observed relative frequencies for less-than and greater-than judgments can be fitted reasonably well by the ogives of the normal probability integral, in early psychophysical literature sometimes referred to as the phi function of gamma or the phi-gamma function. In current applications, the constant method often is employed using only two categories of judgment, "greater than" and "less than"; more reliable results are obtained when "equal" judgments are disallowed.

The constant method is regarded as the most accurate and general of the psychophysical methods. While its use has been illustrated here primarily for the estimation of threshold values, it is widely used for other problems of sensory psychology. The method has been found particularly useful for industrial research in the quality control of food and beverage products, where sen-

sory characteristics of the product play a large role in consumer acceptance.

Direct Psychological Scaling.—Method of Paired Comparisons.—Related to but distinct from the constant method is the method of paired comparisons, developed in 1927 by the U.S. psychologist L. L. Thurstone (*q.v.*). Taken together with Thurstone's law of comparative judgment, the method of paired comparisons provides a model by which sensations may be scaled directly, without reference to corresponding physical measurements of stimuli. In the formulation of Weber ($\Delta R/R = c$) the concern is only with the physical measures of the stimulus *R*. Fechner's proposal ($S = k \log R$) explicitly introduced a continuum of sensation, and allowed indirect "measurement" of sensation by using a functional relation between sensation and physical measurement. Thurstone's model allows direct measurement of psychological events without having first established an intervening quantitative relation between psychological and physical events. One striking feature of the method, thus, is its applicability to the scaling of human attitudes, consumer preferences, aesthetic values and other psychological variables associated directly with no apparent physical counterparts.

In the method of paired comparisons, each one of a set of stimuli is presented together with every other stimulus in the set. The subject is asked to make one of two possible judgments to each stimulus pair, either that stimulus *A* exceeds stimulus *B* or that stimulus *B* exceeds stimulus *A*. The word exceeds is specified by the purpose of the study, so that judgments might be heavier, brighter or louder, or could be more valuable, friendlier or the like. Paired stimuli could be presented many times to only one subject or many subjects may judge each stimulus pair just once. In either case the result is a matrix of relative frequency showing the proportion of times each stimulus was judged higher on the scale than every other stimulus.

From these basic data, scaling proceeds by the law of comparative judgment. It is assumed that a subject's response reflects the momentary subjective value associated with the stimulus, and that the probability distribution of these momentary values is Gaussian (normal), either over numerous occasions for one subject or over a population of homogeneous subjects. This is followed by application of the simplest case of the law of comparative judgment: $\mu_i - \mu_j = z_{ij}$, where μ_i and μ_j are the mean psychological values associated with a pair of stimuli *i* and *j*, and where z_{ij} is the unit normal deviate associated with p_{ij} , defined as the proportion of judgments that stimulus *i* is greater than stimulus *j*. (Note that z_{ij} is uniquely determined from p_{ij} and may be read as an entry in the table of the normal distribution function.) If the numbers z_{ij} are arranged in matrix (tabular) form, the mean values for the columns provide estimates for the n values μ_i . For the case where $n = 4$, the table takes the following form (noting that for z_{ij} may be substituted the quantity $\mu_i - \mu_j$):

$\mu_1 - \mu_2$	$\mu_2 - \mu_1$	$\mu_3 - \mu_1$	$\mu_4 - \mu_1$
$\mu_1 - \mu_3$	$\mu_3 - \mu_1$	$\mu_4 - \mu_3$	$\mu_4 - \mu_2$
$\mu_1 - \mu_4$	$\mu_4 - \mu_1$	$\mu_2 - \mu_4$	$\mu_3 - \mu_4$
$\mu_2 - \mu_3$	$\mu_3 - \mu_2$	$\mu_1 - \mu_3$	$\mu_1 - \mu_2$
Sum: $4\mu_1 - \Sigma\mu_i$	$4\mu_2 - \Sigma\mu_i$	$4\mu_3 - \Sigma\mu_i$	$4\mu_4 - \Sigma\mu_i$
Letting $\Sigma\mu_i = 0$			
Mean: μ_1	μ_2	μ_3	μ_4

Since the zero point to this scale is arbitrary, $\Sigma\mu_i = 0$ may be defined as above, and this yields the desired solution.

Psychological scaling methods typically allow measurement on a scale characterized by equality of intervals, but one with only an arbitrary origin or zero point. As upon the Celsius or Fahrenheit scales of temperature, nominal magnitude of zero does not correspond with absolute absence of that which is measured. On such scales ratio comparisons of measures are not valid. (A substance registering a temperature of 40° C., for example, is not twice as hot as a body with measured temperature of 20° C.)

However, the method of paired comparisons has been extended to provide a rational zero point, and thus to allow for meaningful ratio comparisons of psychological magnitudes. On a scale of consumer preference, the psychological zero point is that psychological value which, if assigned to a consumer item, would

result in consumer indifference toward that item. An absolute scale is established by first assuming the additivity of psychological magnitudes—that (under specified conditions of independence of stimuli) the subjective value for a combination of two stimuli is equal to the sum of the two values associated with the individual stimulus items. The assumption may be stated $\mu_{ij} = \mu_i + \mu_j$, where μ_{ij} is the mean psychological value associated with a composite stimulus, and μ_i and μ_j are the mean values associated with the two component stimuli. There is one such equation for every composite stimulus included in a particular study, and it becomes a matter for empirical test to determine whether the several equations are consistent with subjects' judgments scaled by the method of paired comparisons.

Method of Successive Categories.—Derived from assumptions similar to those for the method of paired comparisons is the method of successive categories. Subjects are instructed to rate each of a set of stimuli by assigning it to one of a group of ordered categories of judgment (usually between five and ten categories). Ratings are to reflect the subjects' judgments concerning the stimulus and are taken as gross indicants of the underlying psychological values associated with the stimulus. Under the assumption that the ratings represent random variables from a normally distributed population of underlying scale values, it becomes possible to estimate the mean and standard deviation of the underlying distribution of subjective values for each stimulus. The method of successive categories has the advantage of requiring just one rating from each subject for every stimulus, in contrast to the method of paired comparisons which requires $n(n-1)/2$ judgments for each of n stimuli. Results from the two methods generally have been found to be nearly identical.

An Alternative to the Fechner-Weber Law: the Power Function.—One of the earliest criticisms of Fechner's psychophysical approach was that of the Belgian physicist J. A. F. Plateau (1801-83). Plateau reasoned that, since the apparent relations among different shades of gray remain *sensiblement le même* when the general illumination is changed, the ratios among the sensations produced by the grays must remain fixed. This, he argued, is more rational than Fechner's view that it is the differences that remain fixed. While Fechner's formulation entails a logarithmic relation between sensation and stimulus, Plateau's assumption entails a power function of the form $S = aR^n$, where sensation S is proportional to a constant power n of stimulus magnitude R ; a is the proportionality factor.

Since the time of Plateau, the power function alternative to the Fechner-Weber law has been revived on several occasions, but never before with such force as that brought to bear by the U.S. psychologist S. S. Stevens. Stevens vigorously attacked the Fechnerian assumption that the just perceptible stimulus difference may serve as a unit of measurement for sensation. As a result of extensive laboratory investigation, a power function has been found to relate psychological magnitude to stimulus magnitude ($S = aR^n$) for more than a dozen distinct psychological continua. Empirical determination of the exponent n has shown it to vary from about 0.3 (for loudness) through unity (for taste, visual length, visual area) and 1.5 (heaviness) to approximately 2.0 (visual flash rate).

The methods utilized in these studies differ sharply from Fechner's psychophysical methods. In the work of Stevens and his students, subjects are required to make direct quantitative estimates of subjective events. The most prominently used of these methods is that called fractionation. The subject is required to adjust one stimulus so as to produce a sensation half (or some other fractional amount) as great as a given standard stimulus.

It seems highly probable that the distinct psychophysical laws, logarithmic and power function, result from application of different measurement methods. By this view, the power function formulation is not necessarily inconsistent with the Fechner-Weber law. Rather, each is valid, but pertains to a unique definition of psychological magnitude, a definition specified by the psychophysical method employed.

PSYCHOSES. A psychosis is a mental illness in which the patient fails to discriminate between stimuli arising within himself and stimuli received from the external world. The healthy personality accurately perceives and evaluates the environment. When the stress of conflict between the self and the environment becomes too great, however, the perceptive and evaluative (ego; *q.v.*) functions of the personality may break down. In such situations the person appears to distort his concept of the environment into a form which is more satisfactory for him; he organizes it into a less confusing place in order to protect himself. In the process he loses contact with reality and becomes psychotic.

Psychoses are rare until adolescence, but thereafter continue to increase in incidence with the advance of age. There is an especially sharp rise at the older age levels. The problems and conflicts of phases of development and stress, such as adolescence, marriage, pregnancy, parenthood, the involutional period and senility, tend to disturb psychological integration and may precipitate a psychotic disturbance in vulnerable persons.

Psychoses present symptoms that have multiple causations and multiple meanings. These are indicative of underlying conflict and represent ways of trying to deal with the conflict. Symptoms may represent attempts to adapt through protective and safety devices, or else they may appear when defenses collapse and disintegrate. Psychotic symptomatology is a manifestation of both regressive and restitutional phenomena. Initial symptoms, such as world-destruction fantasies, hypochondriasis and depersonalization, often represent regression to earlier behaviour patterns or renunciation of the objective world. Later symptoms, such as world-saving fantasies, hallucinations and delusions, may be evidence of a swing toward restitution or toward reintegration of the psychotic ego. The psychotic appears to oscillate between an almost complete loss of object relationships and a striving to re-embrace them.

Symptoms of Psychosis.—Psychotic symptoms may be considered under the following headings:

1. Disorders of perception. A hallucination (*q.v.*) is a misperception (either auditory, visual, olfactory or, less frequently, gustatory). Something is perceived which has no objective reality; for example, voices may be heard when no sound exists. An illusion is a misinterpreted perception in which a sensory impression is received correctly but then misconstrued so that it takes on an erroneous meaning. For example, the rustling of leaves may be interpreted as whispering reproaches; although the rustling is heard, it is given a specific psychological meaning.

2. Disorders of thinking. In autistic or dereistic thinking the mind appears to operate without regard to reality, building up an unrealistic fantasy life and becoming preoccupied with the fantasy to the exclusion of reality. A "flight of ideas" is characterized by a rapid digression from one thought to another, often expressed as words or clauses run quickly together without an apparent logical connection. Perseverations are repetitive expressions of an idea and include verbigations, or repetitions of apparently meaningless words or sentences. A delusion is a false belief which is not susceptible to correction by reason or logic. Thus many patients suffering from delusions of persecution may believe there is an international plot directed specifically against them, and they cannot be shaken from this belief. Patients with delusions of grandeur are convinced they are such exalted figures as Napoleon or Jesus Christ.

3. Disturbances of consciousness. A confusional state usually includes bewilderment, perplexity, uncertainty, disorientation and difficulty in grasping the simplest concepts. Stupor is a state of mind manifested by varying degrees of consciousness but always including diminished responsiveness, either through suspension of

thought processes or through intense preoccupation with internal concerns, withdrawal and loss of reality sense. Delirium (*q.v.*) is characterized by combinations of the above plus illusions, hallucinations and intense fear.

4. Disturbances of affectivity and mood. Affectivity or feeling tone are terms signifying the minute-to-minute variations in the subjective feelings of a person. Mood is a sustained feeling tone over a longer period of time. These emotional states range along a continuum from extreme depression through normal affect to extreme elation. In the most extreme elation reality is completely denied, and attitudes of grandeur and peaceful rapture, detachment and power are assumed. Another dimension of affect includes panic, consisting of marked fear and a tendency toward disorganization of the personality. Characteristic of all these affect states (elation, depression, panic) is their inappropriateness; that is, the feeling tone is not appropriate to the patient's life situation.

5. Disturbances of activity. Marked increases or decreases in the rate of mental and physical activity are common. Hyperactivity includes excessive restlessness, pacing, agitation and excitement. The extreme of diminished activity is called waxy flexibility, in which the limbs are maintained in fixed poses for long periods of time.

Defense Mechanisms.—Although the ego defends itself against overwhelming anxiety with defense mechanisms, the mechanisms themselves may become of pathological degree.

1. Rationalization is a form of self-deception by which a person acclaims in a manner acceptable to himself an act, thought or feeling that in actuality has a different and more unacceptable motive. The real reason thus remains obscure. Although rationalization is commonly used by all people, such self-deception may become a full-fledged delusion if carried to an extreme.

2. Projection is a mental technique whereby a person unconsciously externalizes some of his own thoughts or feelings or inadequacies. He thus defends himself from his unacceptable impulse by attributing it not to himself but to another. Thus a person who cannot face his own hostility may attribute it to another and accuse the other of hostile designs against him. This mechanism characterizes the formation of paranoid reactions (*see below*).

3. Autism, withdrawal into fantasy and regression (a moving back toward less mature but more comfortable levels of personality development) are protective devices but may lead to psychosis formation.

4. The process of internalization or introjection involves a turning inward upon the self of certain feelings and attitudes which thereby may produce depression. (*See also DEFENSE MECHANISMS.*)

Causes of Psychosis.—The causes of psychoses appear to be multiple. They include somatic (physical), biological, psychological (intra- and interpersonal) and sociocultural factors, all of which affect attitudes, feelings and behaviours. Studies of psychological causes stress the importance of the mother-infant relationship, inability and/or lack of opportunity for the child to obtain gratification of his basic needs, and defective development of a sense of reality. Extreme maternal deprivation during the first few months of life, caused either by lack of a mothering figure through loss or by an unusually barren mother-infant relationship, generates unbearable tensions. Since deprived children have had no one with whom to relate when relationship was most important, the warmth and security derived from relating to another human being are lacking. Genetic studies indicate that a specific potential for reacting to personality stresses in a specific way can be inherited; that is, it is possible to inherit a constitutional predisposition to psychosis which is then stimulated or extinguished by other etiological factors.

In addition to the basic determinants, there are a variety of factors that may precipitate a psychosis. These may be obvious reproductions or re-enactments of earlier stresses, or they may be less apparent and seemingly irrelevant events whose relationship to previous stress is obscure. Frequently precipitating factors are organic, such as alcohol and other drugs, infectious

processes, endocrine and vitamin deficiencies, physical defects and brain injuries. Other precipitating factors appear to be manifestations of stressful times and events of life, as marriage or pregnancy. Overwork has frequently been implicated, but it is a symptom rather than a cause.

Organic Psychoses.—The psychoses are divided into two main categories, organic and psychogenic (for which *see below*), according to the presence or absence of discernible organic factors. Organic psychoses result primarily from pathological changes in the central nervous system. They are divided into acute and chronic types. The acute group includes those reactions which come on suddenly, last for a limited time and then disappear. The chronic diseases are slower in onset and tend to produce more lasting effects, which do not appear to be reversible but become stationary or gradually progressive.

The brain is particularly susceptible to physiochemical changes. It is dependent on a large flow of well-oxygenated blood, and since its metabolic activity is high, its oxygen consumption is also high. The brain has a small oxygen reserve and cannot withstand oxygen deprivation very long. It can expand little, yet is suspended and quite movable, subject to injury and sensitive to any noxious stimuli. Thus a state of reduced cerebral competence from whatever cause predisposes the individual to the development of an organic psychosis: (1) personality change, defects in judgment and moral code, tendency toward egocentricity; (2) disturbances in memory, especially for recent events, disorientation for time, place and person; (3) emotional instability, irritability and frequent shifts in mood; (4) exaggeration of previous personality problems (persons who have been aggressive tend to become overwhelmingly hyperactive, whereas persons who have been quiet and reserved tend to withdraw even more); (5) diminished tolerance to medications (more severe reactions to sedatives, other drugs).

In addition to acting as a specific cause or precipitating stress for the development of a psychosis, organic brain disease may interfere with and impinge upon the healthy integration of the personality. The result is impaired ego function, and the symptoms are a manifestation of ego disintegration. A less competent ego then permits the release of previously ward-off impulses which overwhelm the ego and lead to a psychosis.

The following are significant clinical entities:

1. Infectious processes. A meningitis (*q.v.*) may be either intracranial or systemic. Although commonly an acute reaction, some types of meningitis are long-standing, slowly developing diseases. Syphilitic meningoencephalitis, also called general paresis, an infection not only of the meninges but also of the brain itself, may require years to develop (*see VENEREAL DISEASES: Syphilis: Neurosyphilis*).

2. Intoxications. A variety of drugs or poisons produce acute and chronic symptomatology. Bromides, barbiturates, lead and alcohol taken over a prolonged period of time may lead to psychoses. Profuse and frequent imbibition of alcohol followed by sudden withdrawal and accompanied by a nutritional deficiency leads to a condition known as delirium tremens. Korsakoff's psychosis, associated with alcoholism, is in reality due to a severe vitamin B deficiency and is characterized by amnesia, disorientation for time and place and falsification of memory (*see ALCOHOLISM*).

3. Injuries. Severe head injury may produce an acute syndrome known as traumatic delirium or a chronic personality disturbance such as seen in the prize fighter who is "punch drunk."

4. Metabolic disorders such as hypoglycemia (a deficiency of sugar in the blood) and certain swellings or growths (brain tumours and cysts) may bring about a psychosis.

5. Degenerative diseases. Advanced age may be associated with a degenerative disease of the brain which leads to dementia, a psychotic disturbance characterized by progressive impairment of basic mental capacities. In these cases the brain cells literally "wash away" and disappear (*see DEMENTIA*).

6. Circulatory disturbances. One of the commonest disease processes expressing itself in both acute and chronic psychotic forms is cerebral arteriosclerosis. In this condition there is

gradual or fairly rapid hardening of the blood vessels of the brain, and deposits of fat in the deteriorating vessel wall tend to narrow or almost obliterate the vessel, thereby obstructing the flow of blood. When less blood is carried to the brain its nutritional status is affected and psychosis appears. There is often a fluctuation in the course of cerebral arteriosclerosis, and the patient often recognizes his decline, in contradistinction to other organic maladies where there is no insight.

The treatment of an organic psychosis depends on its cause, and each is handled individually. Both physiological and psychological therapies are employed, ranging from vitamins, medications and surgical procedures to the establishment of emotional security and an increasing sense of self-esteem.

Psychogenic Psychoses.—Disorders of psychogenic origin appear to be free of structural, anatomical or physiological changes and are the result of disturbed psychological experience. The six major psychoses of psychogenic origin are divided into two distinct but by no means mutually exclusive types, the affective reactions and the thought disorders. In the former, mood disturbances are dominant; in the latter, there is a predominant disturbance in the capacity to think and judge and the power to reason. The three affective reactions are involutional depression, manic-depressive psychosis and psychotic depressive reaction. The three thought disorders are schizophrenia, paranoia and paranoid state.

Affective Reactions.—An involutional depression is a depression coming on in the so-called involutional period of life (*i.e.*, approximately 40–60 years of age in women, 45–65 in men). It is often accompanied by agitation, usually represents the person's first "breakdown" and occurs in people whose premorbid personalities are characterized as energetic but inhibited, compulsive and over-conscientious, chronically worried, inflexible and sensitive.

A manic-depressive psychosis, as the name suggests, may be made up of both manic (hyperactive, elated) phases and depressive states, alternating with one another or occurring haphazardly without any particular order. Instead of alternating, all episodes may be manic, or all may be depressed. These episodes are usually cyclic in nature and may come on every few months or every few years with reasonable regularity. The disease occurs in young people (early 20s) and may continue intermittently for many years, each attack lasting a few weeks or a few months. The manic phase may represent a defense against a basic depression; certainly the swings from one phase to another give credence to the homogeneity of the two elements. The symptomatology of the manic is characterized by exaltation and excitement, loquaciousness and rapid association of ideas. Psychomotor activity is described as overactive. The depressed phase, on the other hand, is usually characterized by psychomotor retardation; *i.e.*, movement and mental activity are slow and there is an inhibition of the stream of thought.

The prepsychotic personality of the manic-depressive is distinguished by its lability, mood swings and unpredictable oscillations of emotion.

The term psychotic depressive reaction describes a depression of psychotic proportions, arising as a direct result of one or several specific precipitating stresses. It may come at any age, and is often an isolated, single episode in a person's life.

Thought Disorders.—Schizophrenia is a term coined by E. Bleuler in 1911, from two Greek words meaning "splitting of the mind." As with the others, this disorder represents an expression of the total reaction of the person to internal and external stress. There is a breakup in the normal synthesis of thought, and part of the split takes place between the thought process and the affect connected with it. In its most definitive form the schizophrenic syndrome is made up of: (1) a disorder of association—the train of thought does not seem to follow a usual rational pattern; (2) a disorder of affect—the feeling state is inappropriate to the situation, to the particular thought or idea expressed; (3) autistic thinking—withdrawal into self and a fantasy world; and (4) ambivalence—indecision or complete blocking because of two conflicting feelings or two opposing impulses.

Emerging from these manifestations are a host of varied symp-

toms and signs including poverty and disharmony of feeling tone, inability to relate to another person and delusional or hallucinatory mental content or both. A schizophrenic person may appear dull and apathetic. He may be catatonic and stay in one position over a long period of time. He may exhibit mutism, impulsive or stereotyped behaviour and occasional phases of stupor or excitement; or he may be preoccupied with delusional thoughts with behaviour corresponding to these thoughts. In general there may be mixtures and combinations of symptoms, attitudes, expressions and patterns, so that it is difficult to classify schizophrenics into subtypes or to place them in various subdivisions (*see* SCHIZOPHRENIA).

The paranoid psychoses are characterized by delusions of a persecutory or grandiose nature, with varying degrees of ego disintegration. In true paranoia there is usually one basic, well-systematized delusion, while the rest of the ego remains reasonably intact. The true paranoiacs are rarely identified, as they usually manage to conceal their delusions and to function adequately. Paranoid states involve a more elaborate delusional system in which the delusions are less believable and more loosely organized and lead to a more disintegrated ego structure. During the paranoid episode the patient may be obstreperous and hostile (*see* PARANOID REACTIONS).

The bridge between the paranoid psychosis and the schizophrenic psychosis is an entity known as paranoid schizophrenia. In the most serious forms the delusions are poorly organized, bizarre and contradictory, and ego disintegration proceeds at a rapid pace. Paranoid schizophrenics range along a continuum from relatively harmonious ego co-ordination to almost complete ego decomposition and loss of control. The paranoid schizophrenic is potentially dangerous to himself or others because of his feeling that others are against him and because of his bizarre reactions to this thought.

Treatment of the psychogenic psychoses is varied and variable. Several therapies usually are combined in managing a particular syndrome with one or more therapeutic procedures utilized at specific times for specific reasons.

Many patients with psychosis require hospitalization; some do not. Outside a hospital, psychotherapy, environmental manipulation and the administration of drugs are valuable. In a hospital, a program is devised to include individually prescribed activities for the patient and certain helpful attitudes on the part of the ward staff; in addition, somatic therapies such as electroshock and drugs (major and minor tranquilizers) are employed when necessary. The affective psychoses, particularly the involutional depressions, respond more favourably to electroshock than do the thought disorders. In the paranoid conditions sometimes insulin and occasionally lobotomy (surgery on the brain) have been used, and favourable results with drug therapy have been reported. However, the basic treatment in all the psychoses consists of psychotherapy plus the provision of a "therapeutic milieu"—a scientifically manipulated environment within which ego reorganization may take place. Such a milieu encourages creativity and socialization by means of a structured program of activities and the opportunity for the patient to share some of the responsibilities of ward life with the staff. Thus the total experience of living is utilized in the process of getting well.

Childhood Psychosis.—Childhood psychosis is an uncommon but severe form of ego disturbance which becomes apparent in the early years of life (before puberty). Onset may be sudden or insidious. Symptoms include withdrawal, negativism (refusal to do whatever is asked, or doing the opposite of what is expected or desired), anxiety, stereotyped behaviour and a tendency toward an abandonment of reality. In infancy the baby may be apathetic and fail to react emotionally to being approached or when picked up.

Etiologically the lack of an affectional tie between infant and mother appears to be important. Often the mother (or both parents) as well as the child require treatment. Institutional care for the child is sometimes indicated. For other types of mental disorders, *see* NEUROSES. For treatment, *see* PSYCHIATRY; PSYCHOANALYSIS; PSYCHOTHERAPY; NEUROPHARMACOLOGY AND

PSYCHOPHARMACOLOGY. See also PSYCHOLOGY, ABNORMAL; and references under "Psychoses" in the Index.

(P. M. MA.)

PSYCHOSOMATIC DISORDERS are a class of bodily reactions, e.g., diarrhea, asthma, and rashes, observed in emotional disturbances. See PSYCHIATRY: *History: Psychosomatic Medicine*; PSYCHOLOGY, ABNORMAL: *Abnormalities of Behaviour: Neurotic Reactions*.

PSYCHOTHERAPY in its broadest sense is the systematic effort of a person or group to relieve distress or disability by influencing the sufferer's mental state, attitudes and behaviour. Drugs may be used as adjuncts, but the healing influence is exerted primarily by words and actions that are believed by sufferer, therapist and the group to which they both belong to have healing powers and that create an emotionally charged relationship between them. Psychotherapeutic methods are used to treat all forms of suffering in which emotional factors play a part. These include behaviour disorders of children and adults; emotional reactions to the ordinary hardships or crises of life; psychoses, characterized by derangements of thinking and behaviour usually so severe as to require hospitalization; psychoneuroses, which are chronic disorders of personal functioning often accompanied by bodily symptoms of emotional strain; addictions; and psychosomatic illness, such as gastric or duodenal ulcer and certain skin diseases, in which tissue damage is caused or aggravated by emotional components. Since loss of morale contributes significantly to the degree of disablement of all chronically ill or handicapped persons, psychotherapeutic principles are emphasized in rehabilitation programs.

Historical Survey.—Early psychotherapeutic theories and methods were based on either the religio-magical or the naturalistic view of mental illness. The former, originating before recorded history, regarded certain forms of personal suffering, or of alienation from one's fellows, as caused by an evil spirit that gained entrance into the sufferer because he had sinned or through an enemy's curse. The curse could be lifted or the transgression atoned for, leading to expulsion of the evil spirit, by the participation of the victim and his group in suitable rites, under the leadership of a priest-physician, the medicine man or shaman. Thereupon the victim's health was restored and he was once more accepted by his group. The tradition of supernatural healing remained strong and finds its modern expression in, for example, healing shrines and numberless cults led by healers whose claims are accepted only by their devotees.

The naturalistic tradition viewed mental illness as a phenomenon that could be scientifically studied and treated, like other forms of illness. Treatment consisted in measures to promote bodily well-being and mental tranquility. The earliest surviving expression of this concept is in the writings attributed to Hippocrates in the 5th century B.C. Though largely eclipsed in the middle ages, at the turn of the 19th century it again began to come to the fore under the leadership of the great French physician Philippe Pinel. For him, many forms of insanity were the results of excessive exposure to social and psychological stresses, and he tried to help the insane regain their reason through "moral treatment," which included close, friendly contact, intimate discussion of personal difficulties and a planned program of purposeful activities. The popularity of moral treatment depended upon the belief that insanity was curable by psychological influences. As the theory gained ascendancy that mental illness was caused primarily by organic disease of the nervous system rather than by the stresses of life, faith in its curability by psychological means declined and, starting in the middle of the 19th century, mental hospitals tended to degenerate into custodial institutions, which most of them continued to be until the mid-20th century.

Psychotherapy of nonhospitalized patients in the naturalistic tradition was not distinguishable from ordinary medical practice until the latter half of the 19th century. The emergence of psy-

chotherapy as a specialized treatment probably is traceable to the dramatic demonstration by Franz Anton Mesmer (q.v.) in the late 18th century that many symptoms could be made to disappear by putting a patient into a trance. Although his theories and methods were soon discredited, mesmerism was the precursor of hypnotism, which became a widely used psychotherapeutic method. Through it Josef Breuer and Sigmund Freud (qq.v.) made the epochal observations on the relationship to later mental illness of emotionally charged damaging experiences in childhood. From these discoveries grew the theory and practice of psychoanalysis, which, with its many modifications, immensely influenced the subsequent development of psychotherapy.

Despite the widespread recognition that the groups to which a person belongs powerfully affect his attitudes and behaviour, the traditional medical emphasis on the privacy of the doctor-patient relationship slowed general acceptance of group psychotherapy. Though foreshadowed as early as 1905 by Joseph J. Pratt's group treatment of tuberculosis patients, only a few physicians practised group therapy before World War II. The large numbers of soldiers requiring psychotherapy compelled psychiatrists to try to treat them in groups, and the use of group methods proved so effective that they developed rapidly in the postwar years. During this period, two societies and two journals devoted exclusively to group therapy appeared in the United States alone. The professional acceptance of the importance of group influences led to the development of social or milieu treatment for hospitalized patients, based on the recognition that all aspects of institutional life had therapeutic potentialities. This gradually began to transform mental hospitals from custodial institutions into therapeutic communities.

The rapid growth of group therapy was one manifestation of a striking upsurge of public interest in mental health, especially in the United States following World War II, leading to a demand for psychotherapy that went far beyond the capacity of the medical profession to meet it. As a result, members of related disciplines, particularly clinical psychology and psychiatric social work, received increasing recognition as competent to treat certain types of sufferers.

Psychiatrists continued to have responsibility for treatment of the hospitalized insane and patients in psychiatric clinics. They also enjoyed the highest prestige as private practitioners of psychotherapy. Other physicians continued to practise effective psychotherapy of an informal sort on the large proportion of their patients whose bodily complaints were associated with emotional stress. Clinical psychologists and psychiatric social workers treated patients or their families under psychiatric supervision in mental hospitals and psychiatric clinics for adults and children. In addition, members of each profession used methods analogous to, if not indistinguishable from, psychotherapy in certain institutional settings without medical supervision. The type of person or problem with which psychologists and social workers dealt depended largely on the settings in which they worked. Psychologists in educational institutions counseled children, adolescents and young adults; social workers did casework with clients of social agencies, whose personal difficulties tended to be bound up with environmental stresses. The exact limits of the various fields of competence of these disciplines remained vague and the jurisdictional problem became more acute as psychologists and social workers in the larger cities entered independent private practice in direct competition with psychiatrists.

A significant development during this period was the growing *rapprochement* between naturalistic psychotherapy and religiously oriented psychotherapy in the form of pastoral counseling. As psychotherapy became more popular, certain persons came to seek it as a means of achieving a fuller life and finding personal solutions to the general problems of human existence. Psychotherapists thus were faced with questions that traditionally lay in the province of philosophy and religion. At the same time, parishioners put increasing demands on their ministers for help with personal problems, leading the latter to turn for help to the newer insights of psychotherapy. Both groups saw resemblances between the moral and spiritual conflicts or emotional responses to

the crises of life, which were the primary concern of the pastoral counselor, and the issues raised by patients in psychotherapy.

The variety of therapeutic practitioners, was paralleled by a wide diversity of theories of mental illness and methods of treatment. The preferred form of psychotherapy in different cultures seemed to accord with the characteristic pattern of social interaction. Psychotherapy in Germany and the U.S.S.R. tended to be directive, while in the United States permissive, democratic methods had a higher prestige. Within a given culture, furthermore, patients of different socioeconomic levels tended to receive the type of psychotherapy that accorded best with their typical views of treatment. One study of patients in psychiatric treatment in New Haven, Conn., in 1951, for example, found that about half the upper- and middle-class neurotics received insight therapy (see below) as compared with only 5% of the lower-class neurotics. This seemed related to characteristic differences in the conceptions of these classes as to what constituted treatment.

The existence of so many theories and techniques was an indication of the need for research, which received extensive public and private support following World War II.

Features Common to All Forms of Psychotherapy.—There is no convincing evidence that the results of one form of treatment are better than any other, lending plausibility to the supposition that their underlying similarities might be more significant than their apparent differences. Despite differences in emphasis, most schools of psychotherapy agree that mental illnesses are, at least in part, expressions of chronic states of anxiety and frustration, related to unsolved inner conflicts and unsuccessful ways of dealing with other persons. Though genetically or physiologically caused vulnerabilities might contribute to the difficulties of these patients, unfortunate early experiences with family members and other emotionally significant persons are believed to play a major role.

Chances of successful treatment are generally held to be related to the degree of the patient's emotional involvement in the treatment process. This is influenced by the intensity of his suffering and by his faith in the therapist and the treatment method. The patient's expectancy of help is enhanced by the therapist's ability to convince the patient that he understands him intimately and is dedicated to his welfare. Personal qualities of the therapist seem important in the development of a successful therapeutic relationship.

The close, confiding relationship between patient and therapist, including the shared expectancy that the patient will be helped that is common to all forms of psychotherapy, is probably healing in itself. It tends to allay the patient's anxieties and bolster his morale, resulting in direct relief of bodily symptoms due to emotional tension. In addition, it helps him mobilize the courage necessary to give up habitual but unsatisfactory ways of feeling and behaviour and search for better ones. The search is aided by the fact that the therapist or therapeutic group represent certain values and principles of conduct with which the patient can compare his own and adopt what is helpful to him. This usually occurs not through deliberate choice but more or less unconsciously, just as children take over behaviours and attitudes of their parents, which then become integral parts of their own personalities. Psychotherapy thus is essentially a process of re-education, both emotional and intellectual, through which the patient develops better patterns of adjustment to life.

Major Forms of Psychotherapy.—Psychotherapies differ primarily in the nature of the activity that mediates the therapeutic relationship. The variety of these activities is bewildering, but they may be classed as individual or group, depending on whether or not the therapist treats more than one patient at a time. Both forms can be divided roughly into methods that seek to alleviate the patient's distress or teach him more satisfactory behaviour through direct interventions, and those that try to facilitate his over-all emotional growth and capacity for responsible behaviour. Many psychotherapeutic methods contain an admixture of both, and most psychotherapists emphasize one or the other with different patients, depending on the nature of their difficulties.

Individual Psychotherapies.—Individual psychotherapeutic methods for influencing patients directly include giving advice, persuasion, suggestion, and training in specific curative activities. Such efforts frequently involve the use of hypnosis (*q.v.*) to heighten the therapist's influence over the patient, and often include efforts to change his social environment so as to reduce the stresses it places upon him. Behaviour therapies are aimed at correcting specific pathological emotional states or behaviour patterns by appropriate countermeasures. They are based largely on the conditioned-reflex theory of I. P. Pavlov (see **CONDITIONING; REFLEX**) and on other theories of learning. Irrational fears, for example, may be extinguished by evoking them while the patient is completely relaxed, or a craving for alcoholic beverages may be abolished by making the patient nauseated when he tastes them.

Individual therapies that aim to foster a patient's general personality growth emphasize helping him to gain insight into his feelings and behaviour. They are based on the assumption that, since symptoms of emotional illness are expressions of flaws in the patient's over-all approach to life, permanent relief requires major personality change. To facilitate this they try to create a therapeutic situation that will enable the patient to express himself with complete freedom, while the therapist maintains a consistent, warm, nonjudgmental interest. Feeling himself understood and accepted by someone whom he admires and to whom he feels close, the patient will progressively dare to reveal those shameful or frightening aspects of himself that he has pushed out of awareness. As his self-understanding increases, his self-esteem will grow and he will become more spontaneous, enabling him to relate more flexibly and appropriately to persons important to him. Thus he will derive increasing satisfaction and security and his distress will diminish, leading to further gain in his sense of self-worth. In this way a beneficial circle is set in motion, resulting in increasingly deep and permanent improvement.

Some schools of psychotherapy hold that the consistent, warm "unconditional positive regard" of the therapist for the patient is sufficient to produce these changes. Related to these are "existentialist" schools that view therapy as an encounter between therapist and patient, in which the former's healing power lies in his ability to enter fully into the patient's experience, however painful. This aids the latter to escape from his self-centredness and transform his neurotic guilt into normal guilt. Therapies in the psychoanalytic tradition, while also emphasizing the importance of the therapeutic relationship, try to help the patient understand and master his feelings by labeling and analyzing them. They differ in their concepts and in the relative emphasis placed on different types of material produced by the patient. Traditional psychoanalysis emphasizes the use of dreams as short cuts to the patient's deeper feelings. It also puts great stress on helping the patient to rediscover, re-experience and "work through" the traumatic emotional experiences of early life in which his current difficulties are believed to originate. Hypnosis may be used to facilitate this, although Freud believed free association (see **ASSOCIATION, MENTAL**) to be more effective. Later modifications of psychoanalysis put more emphasis on analysis of the patient's current problems, and some emphasize helping the patient to gain a better philosophy of life. All agree that in an intimate, prolonged relation with the therapist, the patient will eventually experience toward him the feelings that trouble his relationships with persons emotionally close to him in his past and present life. Since both therapist and patient can observe these "transference reactions," as Freud termed them, exploring their inappropriateness is deemed a powerful means of resolving them. At mid-century, the advent of consciousness-altering drugs like *d*-lysergic acid diethylamide (LSD-25) led to widespread experimentation with them, to help patients achieve a fuller, more emotionally charged awareness of their inner experiences, including memories of repressed traumatic childhood events. These drugs also were used to promote rapport with the therapist.

Group and Social Therapies.—Group therapeutic techniques are as varied as those of individual therapy, and similarly tend to stress either alleviation of members' distress by direct measures or creation of a group atmosphere conducive to increased self-

understanding and personal maturation. Groups of the first type may have any number of members, up to 50 or more. Some are primarily inspirational in that their chief aim is to raise members' morale and combat feelings of isolation by cultivating a sense of group belongingness through slogans, rituals, testimonials and public recognition of members' progress. Certain of these groups have developed into autonomous movements conducted solely by their members. An outstanding example is Alcoholics Anonymous, organized by chronic alcoholics to help themselves. Two other popular directive methods are didactic group therapy, which seeks, through organized discussions of assigned topics, to stimulate group members intellectually so that they will function more successfully; and therapeutic social clubs, which stress development of social skills through participation in self-organized social activities.

The other class of group methods strives to foster free discussion and uninhibited self-revelation. Most use small face-to-face groups, typically composed of five to eight members. Members are helped to self-understanding and more successful behaviour through mutual examination of their reactions to persons in their daily lives, to each other and to the group leader in an emotionally supportive atmosphere. An influential variety of this approach that utilizes larger groups is the "psychodrama" of J. L. Moreno. In this method patients more or less spontaneously dramatize their personal problems before an audience of fellow patients and therapists, some of whom also participate in the dramatic production itself. The dramatization is followed by discussion between players and audience.

Treatment of the family as a group is based on the view that much of the distress of the mental patient is caused by self-perpetuating and self-defeating ways of communicating with his intimates, in which they are equally involved. The therapeutic focus is on the pathological communication network itself.

Social therapy for institutionalized patients represents at once an extension of group therapeutic principles and a revival of the moral treatment of Pinel. Its aim is to make the mental hospital a therapeutic community, all aspects of which will help to restore the patients' mental health. This involves the creation of a cheerful, homelike atmosphere and a full program of occupational, recreational and social activities. It also involves the development of a flexible, democratic social structure in which all members of the treatment staff work as a co-ordinated team and the patients participate responsibly, to the limits imposed by their disabilities, in all phases of hospital life. Through patient government they help make policy decisions, plan and carry out activities and may even have a voice in the handling of deviant or disturbed behaviour of individual patients.

By heightening the patients' sense of personal worth and instituting social controls of behaviour, social therapy in conjunction with drug therapies may lead to a striking decline in violent or disorganized conduct. This makes possible the reduction or even elimination of physical restraints or locked wards. Social therapy programs lead to a more flexible use of hospital facilities, in that some patients can come to the hospital only during daylight hours, others only to spend the evening and night. In many ways social therapy thus lowers the barrier between mental hospital and community, which improves the morale of hospitalized patients by combating their sense of alienation from the outside world, thereby aiding the recovery process.

Integrated treatment programs finally succeeded in bringing about a progressive decrease in state hospital populations. Though admissions continued to rise, discharges rose even more rapidly. This heartening development enhanced hopes for the increasingly successful treatment of the hospitalized insane.

PSZCZYNA, a town in southern Poland and district chief town of Katowice *województwo* (province), lies on the Pszczyzna River, a tributary of the Vistula, 19 mi. (30 km.) WSW of Oswiecim, and is the junction of secondary railways. Pop. (1962 est.) 15,700. Many old buildings have survived, including the Piast Castle, situated in a park of 78 ha. (193 ac.) and containing a museum. One of Poland's two European bison (*zubr*) reserves, established in 1865, is in the nearby Pszczyzna Forest.

A hunting lodge of the prince of Opole stood there in the early 13th century. In 1327 the village, along with the principality of Opole, was pledged to Bohemia. In 1526 the whole of Silesia passed to the Habsburgs and in 1742 to Prussia. In 1847 Graf Bolko von Hochberg bought a huge estate in the district of Pszczyzna (renamed Pless) and was later made Fürst von Pless. At the partition of Upper Silesia in 1921, the whole district of Pszczyzna, with an overwhelming Polish population, returned to Poland. The princely estate was greatly reduced by the Polish land reform; the remainder was nationalized in 1945.

For the Treaty of Pszczyzna (Pless) in 1915 see BULGARIA: History. (K. M. Wl.)

PTAH, Egyptian god, was originally the local deity of the town of Memphis (*q.v.*), capital of Egypt in the 3rd millennium B.C.; to its political importance was due the expansion of Ptah's cult over the whole of Egypt. The Asiatic origin of Ptah suggested by some scholars is extremely doubtful and the Semitic words from which it has been allegedly derived appear in Egyptian not earlier than the 3rd century B.C. In Egyptian belief, Ptah was the creator of the universe and maker of things, therefore also a patron of craftsmen, especially sculptors; the title of his high priest was "supreme leader of craftsmen." Consequently, the Greeks identified him with their Hephaestus, the divine blacksmith. Ptah was always represented in purely human form. The connection between him and the sacred bull Apis was artificial, but Apis had his stall in the great temple of Ptah at Memphis and was called "intermediary of Ptah," that is, intermediary between men and the god.

See M. Sandman Holmberg, *The God Ptah* (1946). (J. Cr.)

PTARMIGAN is the name given to four species of the genus *Lagopus* of the grouse family (Tetraonidae). The rock ptarmigan (*L. mutus*) is slightly larger than a pigeon and exhibits an almost continual change of plumage to match the seasonal change of coloration in its environment. This change has been found to be regulated by hormones under the control of seasonal increase or decrease in the hours of daylight. In spring the mottled plumage is reddish-brown except for the white breast and wings; in autumn brownish-gray; and in winter, white to match the snow. In summer the rock ptarmigan lives in the rocky tundra, feeding on berries and succulent plants. It lays from 6 to 12 eggs, buffy with brown spots, which are incubated by the female but defended by the male. In winter the feet are covered with hairlike feathers that serve as snowshoes for walking over deep snow; in this season the food is tender buds and twigs.

KARL H. MASLOWSKI FROM THE NATIONAL AUDUBON SOCIETY
WHITE-TAILED PTARMIGAN (*LAGOPUS LEUCURUS*) IN SUMMER PLUMAGE

The white-tailed ptarmigan (*L. leucurus*), found in the mountains of Alaska, Canada and in the Rockies of the United States, is a species that has a summer plumage of mottled black and brown with blotches of white. The red grouse (*L. scoticus*) is a larger ptarmigan, confined to Ireland and Scotland, which never becomes white in winter. The

circumpolar willow ptarmigan (*L. lagopus*) has a winter-white plumage, almost the only difference between it and the red grouse. It is migratory and winters as far south as the Canadian provinces. In the mating season the male ptarmigan has a hoarse cry and often battles with rivals.

See also GROUSE.

(W. J. BE.)

PTERIA, the ancient capital of the "White Syrians" of northern Cappadocia, in eastern Asia Minor, which Croesus of Lydia is stated by Herodotus to have taken, enslaved, and ruined (547 B.C.), after he had declared war on Persia and crossed the Halys (Kizil Irmak). Pteria, also the name of the land surrounding the capital, is mentioned only by Herodotus (i, 76) and by Stephanus Byzantinus (Pterion) among the ancients. The identification of Pteria with the ruins near modern Bogazkoy (*q.v.*), once taken for granted, is quite uncertain, for this site, in older times capital of the Hittite Empire, was in the 6th century B.C. of no greater importance than other fortified cities in northern Cappadocia. Since, according to Herodotus, Pteria was not very far from Sinope (Sinop), a position nearer to the Black Sea seems more likely.

(K. BL.)

PTERIDOPHYTA, in earlier botanical classifications the group of spore-bearing plants, also known as vascular cryptogams, that included the lycopods or club mosses, horsetails, ferns and various fossil groups. In more modern classifications the pteridophytes and spermatophytes (seed-bearing plants) are grouped in the phylum or division Tracheophyta. "Pteridophyte" is still used, but only as a term of convenience. See FERN; SPHENOPSIS; LYCOPODIUM; PALEOBOTANY; PLANTS AND PLANT SCIENCE: *Classification of Plants*.

PTEROPSIDA. Ferns, extinct seed ferns, gymnosperms (conifers and allies), and angiosperms (flowering plants) compose this class of vascular plants (phylum Tracheophyta). It is immediately apparent that there is a broad range in the morphology of the group, differences in vegetative characteristics as well as in reproductive features. The production of unicellular spores by ferns (formed in sporangia found on the lower leaf surface of many ferns) stands in striking contrast with the production of seeds by gymnosperms and angiosperms. In older classifications the ferns were more closely aligned with club mosses and horsetails than with the ferns and seed plants. There are, however, certain basic features that indicate affinity between these seemingly unrelated plants.

The principal unifying characteristic of the Pteropsida is the type of leaf. This is the megaphyll, by definition a leaf with a branched venation system. The megaphyll is correlated with the presence of a siphonostele (vascular cylinder enclosing a pith) in the stem axis (only a few ferns and fewer aquatic angiosperms are exceptions to this generality). Also at the level of leaf attachment (the node) on the stem there is an interruption in the vascular cylinder of the stem above the place at which vascular strands diverge into the leaf. These vascular strands are termed leaf traces and the interruptions leaf gaps. In vascular plants possessing primitive microphylls (leaves with an unbranched midvein) there are no leaf gaps. It is thought that the megaphyll represents a modified branch system from an evolutionary standpoint. Developmentally, there is a close relationship between megaphyll and stem, and this fact tends to strengthen the concept of the branchlike nature of the leaf.

A point of difference between the Lycopsida (club mosses and allies) and the lower Pteropsida is in the position of the spore cases (sporangia). For example, many of the true ferns (Filicales) are characterized by large leaves with numerous sporangia on their undersides, whereas the lycopsids possess small sporophylls, each with one sporangium on the upper side. The underside position of sporangia, although prevalent in ferns, is by no means a constant diagnostic feature of the Pteropsida as a whole. In many gymnosperms the microsporangia, which produce pollen, do occur on the underside of microsporophylls of the male or staminate cone. In angiosperms the microsporangia or pollen sacs, usually four in number, are somewhat embedded in the anther of the stamen of a flower.

Megasporangia or ovules (immature seeds) show an even

greater degree of variation in their position on the plant. In some cycads the ovules are attached to sporophylls that are leafy. In the ginkgo or maidenhair tree the ovules appear to be terminal on a modified branch. In many conifers the ovules occur on the upper side of the cone scales (*e.g.*, in pine, fir, spruce). In angiosperms the ovules are enclosed in an ovary in the flower. They become seeds within the mature fruit.

Ferns.—This subclass (Filicinae or Filicinidae) of the Pteropsida comprises both the living and extinct ferns. Four orders are recognized: the Coenopteridales, Ophioglossales, Marattiales, and Filicales. The sporangia of the first three orders differ from those of the Filicales in that the jacket of the sporangium is composed of several layers of cells and in that numerous spores are produced in each sporangium. The Filicales, or true ferns, are characterized by smaller sporangia specialized for spore dissemination. (See FERN.)

Gymnosperms.—For many years the members of this subclass (Gymnospermae or Gymnospermidae) have been referred to as "naked seed" plants because their seeds are not enclosed in an ovary as is the case in the angiosperms. Certainly their seeds are protected, if not enclosed, in some cases. Seeds in the cone of a pine tree, for example, are protected during most of their development. In the past the gymnosperms have been looked upon as a natural group, but the evidence from morphology and paleobotany indicates that the orders within the subclass are rather diverse and probably have existed as separate evolutionary lines for a long time, perhaps from their origin. However, the subclass designation Gymnospermae is maintained in conservative systems of classification. There is one reasonably natural group, the cycadophytes, which includes: the extinct seed ferns (Cycadofilicales or Pteridospermae); with seeds borne on large compound leaves; the cycads (Cycadales), with stocky, relatively unbranched trunks and leathery compound leaves with seeds borne on modified leaflike structures; and the Cycadeoidales or Bennettitiales, an extinct order having certain features in common with the cycads. Both the cycads and the Cycadeoidales occurred in the Mesozoic Era, which is often referred to as the "Age of Cycads." Only representatives of the Cycadales have survived.

The remaining orders, collectively termed coniferophytes, have characteristics rather different from the cycadophytes. They are extensively branched, with simple leaves that may be scalelike. Abundant secondary vascular tissues are formed and seeds are borne on modified branch systems. The orders Cordaitales and Voltziales are extinct. *Ginkgo biloba*, the only surviving member of the Ginkgoales, is known by its bilobed or notched fan-shaped leaves. It is widely cultivated as a park and street tree in many temperate areas of the world not only for its appearance but also for its resistance to the attacks of insects and fungi (see GINKGO). Pines, spruces, firs, and sequoias are familiar trees of the order Coniferales, which reaches its greatest diversity in the Northern Hemisphere, particularly in western North America and eastern and central China (see CONIFERS). The order Gnetales is comprised of three rather diverse genera: *Ephedra*, a shrubby plant of the deserts of the world; *Gnetum*, a tropical, vinelike plant with rather large leaves and reticulate venation; and *Welwitschia*, an extremely bizarre plant growing in a desert region of southwest Africa. *Welwitschia* has a large taproot and two continuously lengthening straplike leaves that persist throughout the long life of the plant. (See GYMNOSPERMS.)

Angiosperms.—This subclass (Angiospermae or Angiospermidae) comprises the flowering plants, whose seeds are enclosed in an ovary. The major crop plants of the world are included here. Two main subgroups have been recognized for decades: the Dicotyledones and the Monocotyledones. Although there is no clear-cut morphological separation between these subgroups, there are certain features that tend to distinguish them. The dicots have two cotyledons in the embryo, leaves with netted venation, and flower parts commonly in multiples of four or five. The monocots have one cotyledon, the major veins of the leaves generally parallel and joined at the tip of the leaf, and the flower parts in multiples of three. Each subgroup is divided into several orders and many families. (See ANGIOSPERMS.) See also PALEOBOTANY; PLANTS AND PLANT SCIENCE. (E. M. GL.)

PTEROSAUR (*PTERODACTYL*), terms applied to members of a group of flying reptiles that flourished in the Jurassic and Cretaceous periods, between (approximately) 150,000,000 and 70,000,000 years ago. The order Pterosauria is one component of the major reptile group of the Archosauria or "ruling reptiles," to which dinosaurs and crocodilians (*q.v.*) also belong and from which birds are descended. Triassic archosaurs tended toward a bipedal gait, thus freeing the "arms" for use in some other fashion; both birds and pterosaurs converted them into wings. In contrast with birds, and as in bats, pterosaurs formed a wing surface by means of a membrane of skin. In bats all the fingers except the thumb support the membrane. In pterosaurs, however, the membrane was attached solely to one elongated finger—the fourth—and extended thence back along the flank to the knee; an accessory membrane lay between the neck and the "arm." The first three fingers were slender, clawed, clutching structures. The pterosaur membrane appears to have been well adapted to soaring and gliding, but lacking, in contrast with bat or bird wings, in maneuverability; disadvantageous, too, is the fact that, in contrast with bats, damage to the membrane at any point would affect the entire wing.

The body was compact; the hind legs were long but slender, and their structure suggests that, unlike birds, pterosaurs were little adapted to upright locomotion or perching but rather, like bats, hung suspended by the hind limbs when at rest.

The neck appears to have been held upright in flight, with the head attached to it at right angles and pointing forward. The skull was lightly but strongly built with fusion of most of the component bones; there was a long slender beak. The eyes were large, and the eyeball, as in many birds, was reinforced by a series of bony plates (sclerotic ring) lying in its walls.

Casts of the interior of the braincase show that the brain was large and apparently comparable to that of birds in pattern; as in that group, sight rather than smell appears to have been the dominant sense. Most remains of pterosaurs are found in marine sediments; it is probable that they made their livelihood by diving for fish, like terns and gulls, and it is difficult to understand how they could have risen from land or water after alighting.

Two major groups of pterosaurs are known. *Rhamphorhynchus* of the late Jurassic Solenhofen slates is typical of the more primitive division, although earlier forms are present in the Early Jurassic (Lias).

Characteristics of this group include the presence of a battery of powerful, sharply pointed teeth in the jaws, relative shortness of the bones supporting the fingers (the metacarpals), and the retention of a long tail, which in *Rhamphorhynchus* is known to have had a diamond-shaped rudder at its tip. *Rhamphorhynchus* had a wing spread of about two feet, and members of this group, confined to the Jurassic, were generally of similar size.

A second group of pterosaurs appeared in the late Jurassic and continued on into the Cretaceous. The typical Jurassic form is *Pterodactylus*, of which numerous examples are known from Solenhofen. This was a small reptile, some specimens being no larger than a sparrow. Diagnostic features include the reduction of the

FIG. 2.—SKELETAL RESTORATION OF PTERANODON

dentition to a relatively few small teeth, elongation of the metacarpal bones, and the shortening of the tail to a mere nubbin. Descendants of the pterodactyl type continued on into the Cretaceous, and were generally of much larger size. They are best represented by *Pteranodon* of the Kansas chalk, in which the largest known specimen is estimated to have had a wing spread of 25 ft., making it by far the largest flying animal of which there is knowledge.

The skull was about four feet in length; the long jaws were toothless and presumably covered by a horny bill; a long crest extended back from the point of attachment of skull to body in weather-vane fashion. Despite its great size, the animal was very lightly built; the wing bones consist merely of a thin shell of bone surrounding a central cavity which was presumably air-filled in life.

No pterosaur remains are known beyond the end of the Cretaceous; their place in nature was taken over by their avian cousins. (A. S. RR.)

PTOLEMAIC SYSTEM, the name given to the explanation of the apparent motion of the sun, moon, and planets formulated by the Alexandrian astronomer and mathematician Ptolemy (*q.v.*; c. A.D. 150). Ptolemy systematized and synthesized the best of the Greek attempts to account for planetary motions in a treatise known from the title of its Arabic version as the *Almagest*, in which he also suggested hypotheses that were not only elegant but superior to previous ones. The resulting geocentric system was accepted in the Western world for over 1,300 years; i.e., until supplanted by the heliocentric system of Copernicus, which was published in 1543.

The Ptolemaic system, in which the earth was considered the centre of the universe, utilized devices called the deferent (a large circle) and the epicycle (a small circle) to account with some accuracy for the movements of the planets in terms of uniform circular motion. The motion of the sun was explained by placing it on the circumference of an epicycle, the centre of which moved uniformly around the circumference of the deferent, taking one tropical year (the period of the sun's apparent rotation from an equinox to the same equinox) to complete the circuit.

C. A. ROMAN

FIG. 1.—PTOLEMY'S LUNAR THEORY

The centre of the deferent coincided with the centre of the earth. However, in order to explain the observed motion of the moon and planets, the system prescribed deferents for these bodies which were eccentrically situated with respect to the centre of the earth. The centre of the moon's deferent was assumed to lie at a certain distance to one side of the earth. The motion of the centre of the moon's epicycle was uniform with respect to a point situated on the opposite side of the earth at an equal

emy's brother Menelaus was defeated and captured in the decisive Battle of Salamis. Antigonos and Demetrius thereupon assumed the title of kings; Ptolemy as well as Cassander, Lysimachus, and Seleucus (*qq.v.*), answered this challenge by doing the same (some scholars believe he did not do so until 305).

In the winter of 306–305, Ptolemy successfully resisted Antigonos' attempt to invade Egypt. The Rhodians, whom he aided in 305–304 when they were besieged by Demetrius, bestowed upon him the honorific surname *Soter* ("saviour") by which he was commonly known afterward. When the coalition against Antigonos was renewed in 302, Ptolemy invaded Palestine but evacuated it on hearing a false report that Antigonos had defeated Lysimachus in Asia Minor. When the news of Antigonos' defeat and death at Ipsus (*q.v.*) became known, he reoccupied the country. The other members of the coalition had assigned Palestine and Coele-Syria to Seleucus after what they regarded as Ptolemy's desertion, and for the next hundred years the question of the ownership of these countries became the standing ground of enmity between the Seleucid and Ptolemaic dynasties.

In 285 Ptolemy abdicated in favour of one of his younger sons by Berenice (*q.v.*), Ptolemy II Philadelphus (*see below*). His eldest (legitimate) son, PTOLEMY CERAUNUS—whose mother, Eurydice, daughter of Antipater (*q.v.*), had been repudiated—fled to the court of Lysimachus, later became king of Macedonia after murdering Seleucus I (280), and perished in the Gallic invasion of 279.

Two years after his abdication Ptolemy died (283). Shrewd and cautious, he had a compact and well-ordered realm to bequeath to his heir. He was a ready patron of letters, and the great library at Alexandria owed its inception to him. He himself wrote a history of Alexander's campaigns, distinguished by its straightforward honesty and sobriety, which, now lost, can be largely reconstructed through the extensive use made of it later by the historian Arrian.

PTOLEMY II PHILADELPHUS (b. 308; king 285–246) became involved soon after his accession in wars with the Seleucid king Antiochus I (280–279 and *c.* 276–272). These wars left Egypt the dominant naval power of the eastern Mediterranean with many new possessions (*see below*). A third war with the Seleucid kingdom (involving also war between Egypt and Macedonia) was less successful, but Ptolemy scored a diplomatic success by persuading Antiochus II to make peace and marry (*c.* 252) his daughter Berenice (*q.v.*). Ptolemy's first wife, Arsinoe I (*q.v.*), daughter of Lysimachus, was the mother of his legitimate children. After her repudiation he married his full sister Arsinoe II (*q.v.*), the widow of Lysimachus. He deified his parents as the "saviour gods," and he and his sister-wife were themselves deified as *theoi adelphoi* ("brother gods") before Arsinoe's death (270). The surname Philadelphus ("brother-loving") was used in later years to distinguish Ptolemy II himself, but properly it belongs to Arsinoe alone, not to the king.

The material and literary splendour of the Alexandrian court was at its height under Ptolemy II, as was the general power of the Ptolemaic Empire. Callimachus (*q.v.*), made keeper of the library, Theocritus, and a host of lesser poets glorified the Ptolemaic family. Ptolemy himself was eager to increase the library and aid scientific research. He was the patron equally of Greek and Egyptian religion. State control of Egypt's economy in its fully developed form dates from his reign. In a decree of 258 he forbade the use of foreign money within his kingdom.

PTOLEMY III Euergetes I (king 246–221), son of Philadelphus and Arsinoe I, reunited Cyrenaica to Egypt at the beginning of his reign (it had been independent since *c.* 258; *see BERENICE*). At the same time he was obliged to open war on the Seleucid king-

dom, where Antiochus II was dead and his sister Berenice had been murdered, together with her infant son, by Antiochus' former wife Laodice, who claimed the kingdom for her son Seleucus II. Ptolemy marched triumphantly into the heart of the Seleucid realm, at any rate as far as Babylonia, and received the formal submission of the provinces of Iran, while his fleets in the Aegean recovered what his father had lost upon the seaboard and made fresh conquests as far as Thrace. This moment marks the zenith of the Ptolemaic power. After Ptolemy returned home, indeed, Seleucus regained northern Syria and the eastern provinces, but the naval predominance of Egypt in the Aegean remained. After his final peace with Seleucus (241), Ptolemy carried on complicated diplomatic intrigues in Greece with the object of disturbing Macedonian power in the country. Egyptian subsidies were given in turn to the Achaeans, League, Sparta, and Aetolia, but direct intervention was not undertaken.

PTOLEMY IV PHILOPATOR (b. *c.* 238; king 221–*c.* 205), son of Euergetes and Berenice of Cyrene, was a wretched debauchee under whom the decline of the Ptolemaic kingdom began. His reign was inaugurated by the murder of his mother, and he was always under the dominion of favourites, male and female, who indulged his vices and conducted the government as they pleased. Self-interest led his ministers to make serious preparations to meet the attacks of the Seleucid king Antiochus III on Palestine, and the great Egyptian victory of Raphia (217), at which Ptolemy himself was present, secured the province till the next reign. The arming of Egyptians in this campaign had a disturbing effect upon the native population of Egypt, so that rebellions were continuous for the next 30 years.

PTOLEMY V EPIPHANES (b. *c.* 210; king *c.* 205–181), son of Philopator and his sister Arsinoe III, was not more than five years old when he came to the throne, and under a series of regents the kingdom was paralyzed. Antiochus III and Philip V of Macedonia made a compact to divide the Ptolemaic possessions overseas. Philip seized several islands and places in Caria and Thrace, while the Battle of Panium (*c.* 200) definitely transferred Palestine from the Ptolemies to the Seleucids. Antiochus after this concluded peace, giving his own daughter Cleopatra to Epiphanes in marriage (193). Nevertheless, when war broke out between Antiochus and Rome, Egypt ranged itself with the latter power. Epiphanes in manhood was chiefly remarkable as a passionate sportsman; he excelled in athletic exercises and the chase.

PTOLEMY VI PHILOMETOR (king 181–145), the elder of Epiphanes' two sons, succeeded as an infant under the regency of his mother, Cleopatra. Her death was followed by a rupture between the Ptolemaic and Seleucid courts, on the old question of Palestine. Antiochus IV invaded Egypt (170) and captured Philometor.

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

PTOLEMY VI, PORTRAIT ON SILVER TETRADRACHM

The Alexandrians then put upon the throne his younger brother PTOLEMY VIII Euergetes II. Antiochus professed to support Philometor, but when he withdrew the brothers agreed to be joint kings with their sister Cleopatra II as queen and wife of Philometor. Antiochus again invaded Egypt (168) but was compelled by Roman intervention to retire. The double kingship led to quarrels between the two brothers in which fresh appeals were continually made to Rome. In 163 Cyrenaica was assigned under Roman arbitration to Euergetes as a separate kingdom. As he coveted Cyprus as well, the feud still went on, Rome continuing to interfere diplomatically but not effectively. In 154 Euergetes invaded Cyprus but was defeated and captured by Philometor. His brother, however, was willing to pardon him and he was allowed to return as king to Cyrene. In 152 Philometor joined the coalition against the Seleucid king Demetrius I and was the main agent in his destruction. The protégé of the coalition, Alexander

Balas (*q.v.*), married Philometor's daughter Cleopatra Thea and reigned in Syria in virtual subservience to him. But in 147 Philometor broke with him and transferred his support, together with the person of Cleopatra, to Demetrius II, the young son of Demetrius I. He himself at Antioch was entreated by the people to assume the Seleucid diadem, but he declined and installed Demetrius as king. In 145 in a battle near Antioch, in which Alexander Balas was finally defeated, Philometor received a mortal wound. He was perhaps the best of the Ptolemies. Kindly and reasonable, he possessed a good nature that seems sometimes to have verged on indolence, but he took personal part, and that bravely and successfully, in war.

PTOLEMY VII PHILOPATOR NEOS, Philometor's infant son, was proclaimed king in Alexandria under the regency of his mother, Cleopatra II (145). Euergetes, however, swooping from Cyrene, seized the throne and married Cleopatra, making away with his nephew. He soon found a more agreeable wife than Cleopatra in her daughter Cleopatra III, and thenceforth there was chronic antagonism between the two queens, the "sister" and the "wife." In the ancient historians Euergetes (nicknamed *Physcon* because of his corpulence) is portrayed as a cruel and evil tyrant. Massacres inflicted upon the Alexandrians and the expulsion of the representatives of Hellenic culture are laid to his charge. But monuments and papyri show him a liberal patron of the native religion and a considerable administrator, reforming in a series of decrees abuses and weaknesses in the internal government. In fact, while hated by the Greeks, he seems to have had the steady support of the native population. But there are also records which show him, not as an enemy, but, like his ancestors, as a friend to Greek culture.

The old Ptolemaic realm was never again a unity after the death of Euergetes II (116). By his will he left Cyrenaica as a separate kingdom to his illegitimate son PTOLEMY APION (*d. 96*), while Egypt and Cyprus were bequeathed to Cleopatra III and whichever of his two sons by her, PTOLEMY IX SOTER II (nicknamed *Lathyrus*) and PTOLEMY X ALEXANDER I, she might choose as her associate. The result was, of course, a long period of domestic strife. From 116 to 108 Soter reigned with his mother, and at enmity with her, in Egypt, while her favourite son, Alexander, ruled Cyprus. In 108 Cleopatra called Alexander to Egypt, and Soter, fleeing, took his brother's place on Cyprus and held his own against his mother's forces. Cleopatra died in 101 and from then till 89 Alexander reigned alone in Egypt. In 89 he was expelled by a popular uprising and perished in a sea fight in the following year. Soter was recalled (88) and reigned over Egypt and Cyprus, now reunited. This, his second reign in Egypt (88-80), was marked by a native rebellion which resulted in the destruction of Thebes (85).

PTOLEMY XI ALEXANDER II, son of Alexander I, was killed in 80 by the Alexandrians after a reign of only 20 days. Ptolemy Apion meanwhile, dying in 96, had bequeathed Cyrenaica to Rome.

In Egypt the son of Soter II, PTOLEMY XII PHILOPATOR PHILADELPHUS NEOS DIONYSUS, nicknamed *Auletes* ("flute-player"), became king (80), while his brother PTOLEMY became king of Cyprus until the Roman annexation of the island, when he committed suicide (58). Auletes' position was precarious, for it was claimed in Rome that Alexander II had bequeathed his kingdom to the Roman people. From 58 to 55 Auletes was in exile, driven out by popular hatred. He worked by bribery and murder in Rome to get himself restored. Meanwhile his daughter Berenice (*q.v.*) ruled in Alexandria. In 55 Auletes was restored by the proconsul of Syria, Aulus Gabinus. He killed Berenice and, dying in 51, bequeathed his kingdom to his eldest son, aged ten years, who was to take as wife his sister Cleopatra VII, aged seventeen.

In the reign of PTOLEMY XIII PHILOPATOR (51-47) and CLEOPATRA VII PHILOPATOR (51-30), Egyptian history coalesces with the general history of the Roman world, owing to the murder of Pompey off Pelusium in 48 and the Alexandrine War of Julius Caesar (48-47). In that war the young king perished and a still younger brother, PTOLEMY XIV PHILOPATOR, was associated as ruler with Cleopatra till 44, when he died, probably by Cleopatra's contriving. From then till her death, her son PTOLEMY XV

PHILOPATOR PHILOMETOR CAESAR (who according to her assertion was the child of Julius Caesar) was associated in her rule; he was known popularly as *Caesarian* ("little Caesar"). (For the incidents of Cleopatra's reign see CLEOPATRA; ARSINOE.) After her death in 30 and Caesarion's murder, Egypt was made a Roman province by Octavian (see AUGUSTUS). Cleopatra's daughter by Antony, Cleopatra Selene, was married in 25 to Juba II of Mauretania. Their son, PTOLEMY, who succeeded his father (*c. A.D. 24-40*), left no issue on his execution by the emperor Caligula (Gaius).

INSTITUTIONS AND ADMINISTRATION OF THE PTOLEMAIC KINGDOM

The Ptolemaic kingdom consisted of Egypt and foreign possessions which varied considerably at different times. The Ptolemaic occupation of Egypt reached, at its limit, to a point south of the Second Cataract of the Nile, while Ptolemaic generals and explorers penetrated as far south along the coast as Somaliland. Several posts established on the western shore of the Red Sea brought Egypt into commercial relationship with Arabia and India, and from the region of Ethiopia elephants were obtained by the early Ptolemies. To the west of Egypt, Cyrenaica constituted part of the kingdom until 96. Cyprus was the principal overseas possession and the last to be relinquished, in 58. Palestine and Coele-Syria were occupied, with brief intervals, till 200. Many of the Aegean Islands were occupied for long periods in the 3rd century, as were cities on the Hellespont and in Thrace. Most of the coastal districts in western Cilicia, Pamphylia, Lycia, Caria, and Ionia were under Ptolemaic control at times during the 3rd century (though always threatened with reoccupation by the Seleucid kings). This overseas empire was the fruit of the domination of the seas by the Egyptian fleet, and with the decline of Egyptian sea power the greater part of these possessions was lost before the end of the 3rd century. Only isolated fragments were retained into the 2nd century, such as Thera, Itanos on Crete, and Methana in the Argolid.

Administration.—The Ptolemaic kingdom was an absolute monarchy of the same general kind as other Hellenistic kingdoms such as the Attalid and Seleucid (see ATTALID DYNASTY; HELLENISTIC AGE; SELEUCID DYNASTY). To the native Egyptians the Ptolemies presented themselves as the legitimate successors of the ancient pharaohs and exercised over them the type of autocratic government traditional in the land. Their Macedonian and Greek subjects, in theory at least, merely acknowledged the king's leadership from free choice. However, the setting up under Ptolemy II of a cult of the living ruler gave the king a claim to universal allegiance. In the court and the army the traditional Macedonian forms were preserved. The other state institutions resembled to a certain degree the usual Hellenistic pattern, but there were features unparalleled elsewhere. Of the royal ministers only one is known with any certainty—the *dioiketes*, specifically the manager of the king's household, which embraced the whole kingdom, for all land outside the Greek cities was treated as forming the royal domain. The competence of this official in both finance and general administration was very wide, if one may judge by the career of Apollonius under Ptolemy II. The titles of a few other departmental officers are known, but almost nothing is known of their functions or comparative importance. On the other hand, the working of the administrative machine in the rural districts of Egypt is well illustrated in the papyrus documents discovered since the end of the 19th century, and from these it has become clear that the system of government was a highly centralized one in which the king and his ministers kept control over every part of the realm.

The administrative division of Egypt was by cantons (*nomoi*) subdivided into districts (*topoi*), each of which comprised so many villages (*komai*). The nomarchs or civil governors of the cantons (about 40 in number) were at first Egyptians, but their authority soon lapsed and their place in the administrative chain was taken by Greek officials with the title of "general" (*strategos*). The latter had at first a purely military function, but before the end of the 2nd century they had exchanged their original duties for the

work of civil administration. They were assisted by finance officers (*oikonomoi*) appointed by the *διοικητες*. Below the nomarchs and generals, there were the native officials of the smaller territorial units—the toparchs and comarchs. All these officials were assisted by secretaries and scribes who through their intimate connection with the control and regulation of taxation and levies played a very influential part in the administration. Thus, for example, the village scribe easily surpassed in importance his nominal superior, the comarch. Government of the foreign territories was regularly by generals or city governors (*ἐπιστάται*) assisted by *οἰκονομοί*.

Economic System.—The chief object of policy in Egypt (and, so far as is known, elsewhere) was to bring about the most effective possible exploitation of the country's resources for the benefit of the king. This was realized by a rigorous implementation of central directives in the villages, which were treated as the basic units of the economy. The peasants, who were compelled by law to remain in their home village, were assigned portions of the royal land to cultivate on lease, seed-grain being provided by the king. As rent they paid to the king's agents the major part of the annual harvest. The threshed grain was then transported by stages to the king's barns in Alexandria whence large quantities were released for export at such times as the market price was favourable for that purpose. Within Egypt the king could use his stores of grain to make payments in kind.

This grain monopoly was the most important feature of the Ptolemaic economic system and the chief source of the king's wealth. As regards other commodities and trades, the royal monopoly was complete in the case of oil (vegetable extract) and partial (in varying degrees) in other cases, such as papyrus, textiles, salt, glass, mining, quarrying, banking, and the rearing of livestock. The object of the monopolies, which affected virtually every form of business, was to fix prices for the benefit of the royal treasury by eliminating or restricting private competition.

Numerous miscellaneous taxes, duties, and imposts (over 200 are known) were also part of the system. In order that the kingdom's resources might be accurately assessed and an appropriate basis determined for taxation, full and continuous records were maintained by the king's officials. The revenue raised by these means was very great, with the result that the kings accumulated a huge treasure, which was still large even after the dynasty's final collapse at the end of a long period of weak government. Moreover, expenditure was heavy. The upkeep of army and fleet, the salaries of the large civil service, the gifts to favourites, the maintenance of religious cults, and many other things had to be provided for. There was also the burden of essential public works, including the repair and improvement of the innumerable irrigation channels along the course of the Nile. This particular work was done by peasants' forced labour.

Hellenization.—The Ptolemies sought to appear as the guardians and upholders of Greek civilization. This policy was carried out for the purpose of increasing their prestige and influence in international affairs and in particular to encourage the entry into Egypt of Greek immigrants. The latter were urgently needed, for the kings at first were not prepared to entrust senior positions in the administration to Egyptians, and as for the army, they believed that it could not be effective unless it contained a large proportion of Greek soldiers. Accordingly they attracted Greek settlers by granting them allotments of land on favourable terms. These allotments were hereditary in return for the settlers' obligation to render military service when required by the king. These settlers (cleruchs) were the counterpart of the military colonists in the Seleucid kingdom. In time of war they filled the ranks of the phalanx, the traditional Macedonian formation of heavy infantry.

To supplement these regular troops the Ptolemies employed mercenary soldiers of various nationalities, willingly paying them at generous rates. The native Egyptians were little used for military purposes until the Battle of Raphia (217), when a critical situation and the lack of sufficient Greek manpower made their employment unavoidable. Thereafter Egyptians were gradually admitted to posts in the administration, and the kings, from neces-

sity, began to make other concessions to their Egyptian subjects. In spite of these changes, the Ptolemies still regarded the small Greek minority as their chief support and continued to foster its interests, even though by the 2nd century Greek immigration had virtually ceased.

Ptolemy I had moved the capital from Memphis to the new coastal city of Alexandria (*q.v.*); one of Alexander the Great's foundations. Under the Ptolemies Alexandria became an international centre of the highest importance. It was only partially Greek in population, and while the Greek citizens enjoyed a privileged status among its inhabitants, they possessed only a limited degree of autonomy. In contrast to the colonizing activity of their rivals, the Seleucid kings, the Ptolemies founded hardly any Greek cities. In Egypt itself there was only one—Ptolemais, near Thebes, in the upper part of the country. The motive for this foundation was doubtless strategic. Ptolemais was a comparatively unimportant place, but it is worth noticing that, unlike Alexandria, it enjoyed the full self-government of the normal type of Greek city. Toward the Greek cities of their overseas possessions the Ptolemies acted in a high-handed fashion; everywhere they installed garrisons, imposed heavy taxes, and disregarded the cities' autonomy. Only the more important Greek cities of Europe and Asia Minor were conceded, as a matter of policy, the status of independent allies.

The Ptolemies manifested their pro-Hellenism principally by a bountiful but carefully controlled patronage of scholars and artists in Alexandria and by following the practice, common among Hellenistic rulers, of endowing new shrines and religious festivals and acting as benefactors of the ancient sanctuaries.

PTOLEMY (CLAUDIUS PTOLEMAEUS) (fl. 2nd century A.D.), celebrated astronomer, geographer and mathematician. Virtually nothing is known of his life, but according to Theodorus Melitoniota of Byzantium Ptolemy was born in the Grecian city Ptolemais Hermii. The period during which he flourished is known from the dates of certain astronomical observations which he made. His main work was carried out at Alexandria and while he certainly observed between A.D. 127 and 145, it may well be that he was still at work as late as 151. Arabian traditions claim that Ptolemy died at the age of 78.

Astronomical Work.—Ptolemy's astronomical work, which exerted so profound an influence on subsequent generations and indeed, for more than 1,200 years after it was completed, was enshrined in his great book *The Mathematical Collection* (*Ἡ μαθηματικὴ συγγραμμή*). This became known, in due course, as *The Great Astronomer* (*Ὁ μέγας ἀστρονόμος*), to distinguish it from a collection of works of Autolycus, Euclid, Aristarchus, Theodosius, Hypsicles and Menelaus which was known as *The Little Astronomer*. The Arabian astronomers of the 9th century referred to his work by the superlative *Megiste* and from this term, with the definite article *al* prefixed, its title became known as the *Almagest*, the name which is still in use today.

The *Almagest* is divided into 13 books. Book i gives, in broad outline, the geocentric system together with arguments in its favour. Book ii contains a table of chords and what is the equivalent of spherical trigonometry with the theorem of Menelaus (fl. c. A.D. 90) as its basis; sample problems are also worked out. Book iii deals with the motion of the sun and the length of the year. Book iv is concerned with the moon's motion and the length of the month and book v deals with the same subjects, as well as discussing the distances of the sun and moon and giving details for the construction of an astrolabe. Eclipses of the sun and moon are dealt with in book vi, as also are planetary conjunctions and oppositions. The next two books, vii and viii, concern the fixed stars, contain a discussion of precession, Ptolemy's star catalogue and a method for constructing a celestial globe. The remaining five books are devoted to the planets and are, in fact, the most

original part of the work.

It was, no doubt, the encyclopaedic nature of the work that rendered the *Almagest* so useful to those who followed and gave the views contained in it so profound an influence. In essence, it is a synthesis of the results attained by Greek astronomy and, of course, our one source of knowledge of the work and hypotheses of Hipparchus (*q.v.*); indeed, it is often difficult to determine which results are due to Ptolemy himself and which to Hipparchus. It is, however, incorrect to assume that Ptolemy himself carried out but few observations, for he extended some of the work of Hipparchus and appears to have used somewhat similar instruments—a type of mural quadrant for determining the altitude of the sun, an armillary sphere (in which the circles were set parallel to their counterparts in the sky and from which, utilizing open sights, celestial latitude and longitude could be read off) and an instrument known as “Ptolemy’s rules” which was designed for measuring the altitude of heavenly bodies.

While Hipparchus had carried out much work on the stars and had completed the first star catalogue, Ptolemy extended this work. The catalogue of Hipparchus contains 850 stars and that of Ptolemy lists 1,022. However, Ptolemy used the observations of Hipparchus and, in order to bring them up to date with his own, had to make a correction for precession; unfortunately, he erred in the annual value which he adopted for this correction. Hipparchus had discovered precession and determined the value as 45" or 46" per year, but Ptolemy obtained a value of 36" which is, of course, far too small (present determinations give 50.26").

On the motions of the sun, moon and planets, Ptolemy followed Hipparchus and took a thoroughgoing geocentric viewpoint, and it was this approach which became dogmatically asserted in western Christendom until, by the 15th century, further detailed observations had made the Ptolemaic system so complex that the validity of such a view became seriously questioned. As is well known, it was Copernicus who took the bold step of proposing a heliocentric system.

Ptolemy considered the earth to be the centre of the universe, and in the *Almagest* he gives various arguments to prove that it must be immovable. Not least, he showed that if the earth moved, as some earlier philosophers had suggested, then certain phenomena should in consequence be observed, and he was able to show that no such observations had ever been obtained.

He accepted the order: earth (centre), moon, Mercury, Venus, sun, Mars, Jupiter and Saturn. He realized, as Hipparchus had done, that the inequalities observed in the motions of these heavenly bodies necessitated a system of deferents and epicycles in order to keep uniform circular motion as the basis. Yet, even so, the observed phenomena could not be fully taken into account. It was here that Ptolemy showed a brilliant ingenuity by introducing the concept of the equant. He supposed that the earth lay a little way from the centre of the deferents for each planet and that the centre of the planet’s epicycle described uniform circular motion around the equant which he placed on the diameter of the deferent but at the opposite side of the centre to the earth and at a distance equal to that by which the earth was displaced on the other. He was thus better able to account for the observed planetary phenomena.

Ptolemy also improved substantially the lunar theory of Hipparchus by varying the distance of the centre of the moon’s epicycle from the earth. The motion, as with the planetary equant, was uniform, but while the centre of the moon’s epicycle rotated around an equant, the position of the latter was on the opposite side of the earth to the centre of the deferent. With this mathematical device he more precisely accounted for the moon’s motion and discovered the inequality of the lunar motion known as evection, an inequality which is due to the rotation of the apse line. He then prepared tables of the moon’s motion, and these were in use down to the time of Copernicus, 1,400 years later. His value for the evection was close to that accepted today, and although his new theory of lunar motion did not fully account for the observations, Ptolemy made every effort to perfect it. He did not, however, discover any further inequality in the moon’s motion, and it was not until the work of Tycho Brahe in the 16th century

that any further development of this kind was made.

Ptolemy realized that the planets were much closer to the earth than the fixed stars, and he seems to have believed in the physical existence of the crystalline spheres to which the heavenly bodies were supposed to be attached. Outside the sphere of the fixed stars, Ptolemy proposed other spheres ending with the *primum mobile* or prime mover, the latter providing the motive power for the remaining spheres which constituted his conception of the universe.

Ptolemy’s text was translated into Arabic for the caliph al-Ma'mun in 827, and other Arabic translations followed. The *Almagest* was also the subject of many commentaries. One in Greek and written by Pappus in the 4th century A.D. is still in existence; a commentary by Theon of Alexandria (fl. 4th century A.D.) was published in Basel in 1538 and in the same year the first edition of the Greek text was also published there. The Greek text which has now superseded all others is that edited by J. L. Heiberg, published between 1899 and 1907.

Mathematics.—The mathematical work of Ptolemy was important and he was a geometrician of the first order. He proposed a new proof in place of that of Euclid on parallel lines; he showed in “Ptolemy’s theorem” (which concerns a quadrilateral inscribed in a circle) how the formulas $\sin(A \pm B)$, $\cos(A \pm B)$ could be derived and how, with this and a few other simple geometrical theorems, a table of chords could be drawn up. Although it appears that the main theorem was actually due to Hipparchus, Ptolemy deals with the whole matter with a conciseness and elegance which it would be hard to surpass, and was able to calculate a table of chords in increments as small as $\frac{1}{2}^\circ$.

In a work entitled *Analemma*, Ptolemy discussed the details of the orthogonal projection of points on the celestial sphere onto three planes which are mutually at right angles—the horizon, the meridian and the prime vertical. The full Greek text has not survived, but there is a Latin translation made by William of Moerbeke (13th century) from an Arabic original. The *Planisphaerium*, which survives only in a Latin translation from Arabic, is concerned with stereographic projection, and here Ptolemy used the south pole as his centre of projection.

He also prepared a calendar (*Phaseis aplanon asteron*) giving the risings and settings of the stars in morning and evening twilight together with weather indications, and a work in two books entitled *Planetary Hypothesis* (*Hypothesis ton planomenon*) still exists, the first book in Greek but the second in an Arabic translation only.

Early commentators mention two separate geometrical works. One, *On dimension* (*Peri diastaseos*), is concerned with proving that there cannot be more than three dimensions of space; the other contains Ptolemy’s alternative proof for Euclid’s parallel line postulate. Ptolemy has also been credited by Simplicius (*c.* 6th century) with a mechanical work, *On Balancings* (*Peru ropon*), while Suidas (*c.* 10th century) claims that he wrote three books on mechanics.

The *Optics*, which contains Ptolemy’s work on optical phenomena, does not exist in the original Greek but only in a Latin translation made from a 12th-century Arabic copy. It appears that the original was in five books, in the last of which Ptolemy deals with a theory of refraction and discusses the refraction suffered by celestial bodies at various altitudes; this is the first recorded attempt at a solution of this observational problem.

He also wrote a treatise in three books on music. This is known as the *Harmonica* and was edited by John Wallis and published in Latin and Greek in 1682.

Geographical Work.—Ptolemy’s reputation as a geographer is mainly due to his *Guide to Geography* (*Geographike Huphegesis*), which, like the *Almagest*, exerted a great influence on future generations. Again, this was due to his scientific approach to his subject and the consequent ease of reference which the book possessed. An eight-book manuscript version was prepared in 1400 and was translated into Latin nine years later. Numerous editions were published in Europe in the 200 years which followed, and the Greek text appeared at Basel in 1533, edited by Erasmus. All these early editions are full of textual errors.

Hipparchus, three centuries earlier, had already pointed out that a map with any pretensions to accuracy could only be prepared by knowing the longitude and latitude of the principal points on its surface. At the time Hipparchus made his suggestions, little information was available and he seems to have contented himself with his method of dividing the then known world into zones, or *klimata* as he termed them. However, Marinus of Tyre (2nd century A.D.), who lived a little before Ptolemy and to whose work Ptolemy refers in his *Guide*, used determinations of position based on itineraries of travelers and other rough methods. In his treatise, which is lost, Marinus discussed the determinations of the authorities he used, but it is not possible now to assess the scientific value of the results he obtained. Ptolemy considered them in general to be satisfactory and used them as a basis for his own work on the Mediterranean countries, although he showed more reserve in accepting them for remoter regions.

Ptolemy's astronomical work and his studies of map projections made him especially fitted for the kind of geographical work he undertook, but his general views were not unlike those of Eratosthenes and Strabo (*qq.v.*). He continued the method, which Hipparchus had originated, of dividing the equator into 360 parts (degrees) and supposing other great circles (meridians) to be drawn through this. His framework consisted also of parallels of latitude. Although Eratosthenes in the 3rd century B.C. had measured the circumference of the earth and had given a value very close to that accepted today, Ptolemy used the later determination of Poseidonius (*c.* 135–50 B.C.) which was nearly 30% smaller, and so his conclusions as to distances were incorrect by this amount. Moreover, as he plotted the positions of many places purely by using measures of distance, many of his values of latitude and longitude were also incorrect. As prime meridian Ptolemy followed Marinus, taking the great circle through what was supposed to be the most western point of Europe, the Isles of the Blest (the Fortunate Islands; corresponding approximately to the Canaries and the Madeira group). He placed the equator too far north and his principal parallel was correct only at Rhodes. In addition, it should be noted that there are some contradictions between the text and the maps in the *Guide*.

In spite of all these faults, Ptolemy's monumental work exerted a great influence. His idea that Asia extended much farther east than is the case strengthened the belief of Columbus that Asia could be reached by traveling westward, and Ptolemy's suggestion that the Indian ocean was bounded by a southern continent was not disproved until the voyages of Captain Cook in 1773. Some of these ideas were probably derived by Ptolemy from Hipparchus.

The *Guide* was divided into seven books. Book i begins with general explanations and there follow corrections made from astronomical observations of some of the results obtained by Marinus. The question of maps and their construction is next discussed, beginning with a conical projection in which the meridians are represented as straight lines all meeting at a certain point (a kind of north pole) and the parallels of latitude (especially that through Rhodes) as circles with the "north" point as centre. Then follows a more elaborate projection, with meridians as actual arcs of a circle. Books ii to vii contain a list of places tabulated according to longitude and latitude. Ptolemy deals here with Europe and the Mediterranean, then Africa, Asia, Palestine, Mesopotamia, Arabia, India, etc. The work is accompanied by maps (usually referred to as book viii).

As a whole, Ptolemy's geographical work cannot be considered "good geography." No mention is made of climate, natural products, inhabitants or peculiar features of the countries with which he deals. Moreover, although Strabo, for example, was well aware of the geographical importance of rivers and mountain ranges, Ptolemy's treatment of these factors is careless and of little real use. However, it is the profound influence which the *Guide* exerted on later generations which makes this work so important from a historical point of view.

PUBLIC ADDRESS SYSTEMS: see HIGH-FIDELITY SOUND SYSTEMS.

PUBLIC ADMINISTRATION is the application of a policy of a state through its government. Once policy is given general legal formulation in statute law, there then remains the task of defining that law and applying it to specific situations. A statute is the product of a law-making agency that is not always in session and whose members are usually selected to represent general attitudes and opinions rather than to possess expert knowledge. Such legislators may adopt a statute to facilitate traffic and may authorize in general terms the regulation of the movement of motor vehicles by specifying reasonable speeds on public streets and highways with due regard to density of population, location of schools and hospitals, and the existence of intersecting streets. The statute will probably provide also for some agency in continuous operation, and presumably with expert knowledge, experienced personnel, and suitable equipment, to translate the general objectives into specific regulations (*e.g.*, as to coming to a full stop at main arteries or obeying light signals) and to enforce the statute and regulations, with penalties for those who violate them.

Public administration is interrelated with public opinion in that it follows upon the decision of the political leaders to undertake or abandon certain activities; with the legislative process in that effective administration may be rendered difficult or impossible by faulty legislation; and with the judicial process since the action of the administrator may be challenged in the courts by a citizen, and the administrative agency may be required, under the terms of a particular statute, to apply to the courts for judicial action against those presumed by the agency to be violating the law. While there is a theory that administration and policy are two separate processes of government, in fact they are constantly merging. This is because policy-making is inadequate if there is no consideration of the means for making the law effective, and administration of a general objective raises questions of choice, and hence policy, in any specific situation.

Administration and Policy.—The problems of public administration reflect, therefore, these interrelations with opinion, legislation, and adjudication. They also reflect the stage of civilization and the time, place, and environment of the particular political unit. Thus, there should be at the top of the administrative structure an official who can speak for, and to, the dominant political power of the society. This need for making the administrative agency subservient to the original intent for which the activity was authorized explains why the chief of an administrative agency at least of national agencies, is generally a politician and nonexpert. He is chosen because he must interpret to the experts what the judgment of those in political power is, and to the politicians and the lay public what the more technical considerations that will affect their political objectives are. The greatest quantity of public administration is in the substantive functions of government such as those of public safety and order, public health, public works, education, the development of natural resources, the care of the handicapped, and the regulation of finance, business, and industry. Roads and harbours are built. Social insurance payments are made. Forests are guarded from fire or disease. Each field of activity has its accumulated technical knowledge, personnel, and forms of organization and procedure. For any particular jurisdiction in which several of these functions are administered, the problem of allocating available revenue to each, determining priorities, and coordinating the application by each agency of policies in which account should be taken of what other agencies are doing is one of the most important responsibilities of the high-

est administrative authority. At this point in the structure and process of government there is a meeting and mingling of political policy, general management, and the conduct of the particular functional departments.

MANAGEMENT

General Staff Work.—The heads of the administration in any jurisdiction have a double responsibility of helping to formulate legislation and of directing and coordinating the administrative agencies. This latter task becomes difficult in those stages of civilization in which many functions are undertaken through government since it includes the proper assignment of activity to organization units and the coordination of several organization units, each of which has some necessary share in the activity but each of which is also likely to develop its own personality, attitudes, and jealousies. Hence, the top administrative policy group, in modern times often called a "cabinet," and its chairman or chief—prime (*i.e.*, "first") minister, premier, or president—need to have the problems that are presented to them analyzed by persons of integrity, competence, and experience. This has come to be called "general staff work" from the influential and famous Prussian general staff. Elements of this important step in the administrative process are to be found wherever government has been effectively used. Thus, planning, which is inherent in the process of formulating policy, becomes essential also in its wise application, whether in the conduct of war, the prevention of epidemics, the facilitation of transportation, or the relief of destitution.

Auxiliary Services.—The responsible political chiefs of administration have been found by widespread experience to need other aids to ensure economical and efficient application of policy. These are agents for obtaining and facilitating the best use of personnel, physical materials and equipment, architectural and engineering services, and finances. Since such tools are aids both to general direction and to the operating officials (who are on the front lines in the field, building highways, waging war, or constructing irrigation projects), they are frequently called the auxiliary services or "housekeeping services."

There is inevitably some clash between such auxiliary agencies with their responsibility to the administrative chiefs for over-all policy, and the particular operating agency, which has enthusiasm for and special knowledge of its own field and is often resentful of controls that are called "red tape." To the operating official, there looms the threat of what is termed in the British civil service the "treasury mind"; its cousin is found in all large organizations in all times and places. To the official who is zealous in pressing forward his project, the scrutiny of some part of it by another agency which has no apparent responsibility for its success or failure is irksome. The auxiliary or general staff official, however, is equally impressed with the necessity of relating the single project to the other activities of the government and of bringing the enthusiasm of the official within bounds. Personnel and budget policies illustrate the fact that auxiliary and general staff services (which intermingle through day-to-day activities) are more than narrow technical matters. They are of central importance in the operation of any political system.

Personnel.—Long and varied experience in all parts of the world has demonstrated the necessity, for effective administration, of a reservoir of accumulated knowledge of the administration of a function—a knowledge that can be obtained only from persons of ability and integrity who have been given an opportunity for a career in administration. That is not the only reason why spoils systems, wherever they exist, have been disastrous (except in situations in which they may have served as alternatives to more costly revolutions). Their primary evil is that they undermine any use of parties and legislatures as reasonably accurate instruments of recording political sentiment and ideas, since they replace the relationship of agency for the public by agency for the chief spoilsman and turn responsible public affairs into irresponsible private rackets. Their administrative evil is that they prevent the accumulation of knowledge that only experience can give. No person of ability and integrity would be willing under spoils condi-

tions to seek a satisfying career, and inevitably the agency sinks in effectiveness and in public confidence. Even in revolutionary conditions a new government is generally forced to rely upon such officials as it can find for carrying on those services necessary for the safety and welfare of populations—especially in a society partly urban. The knowledge required here is not only the knowledge of a substantive problem, such as preventive medicine or highway construction, but the more subtle knowledge for which long experience inside the institutions is required. This is the knowledge of who knows what, of how to use procedures and codes to hasten or delay business, of how to avoid arousing group and individual jealousies, of "moving through the correct channels," and of winning the consent of all those whose support is needed. The term "bureaucracy" is sometimes given, often in disparagement, to governments in which the "permanent" or "career" officials exercise or condition power. Such a dependence on officials, however, is inevitable and necessary in governments exercising many and interrelated functions.

The selection and training of civil servants has therefore been an important problem of government since early times. The system of widespread recruitment on the basis of examinations in the classics was a feature of the government of China for hundreds of years. The training of officials for the administrative posts in the mediaeval papacy and empire included courses in such universities as Bologna and Naples. The palace school of the Ottoman empire was the nursery of the civil, military and naval officer classes. The ruling families of the German principalities founded universities in which their civil servants (often jealously opposed by the feudal nobility) were educated. In both 19th-century Germany and France, the rise of a larger and more varied civil service was accompanied by the development of opportunities for secondary, university and specialized education that reflected also the enlargement of the middle class. The *École Libre des Sciences Politiques* in Paris and the development of careers in municipal administration in Germany illustrate these tendencies. The Trevelyan-Northcote report on the civil service in Great Britain in 1853 was influenced by such educators as Benjamin Jowett of Balliol and John Stuart Mill. The expansion in the functions of government in the United States prior to World War I created an interest in the education of administrators which revived strongly with another expansion in the decade 1930-40.

In general, educational qualifications for administration reflect the general social conditions of the time and place and the classification of the positions to be filled. A more fluid and democratic society opens its opportunities for secondary and higher education widely and this tends to prevent the formation of a special official caste sheltered by inherited privileges. The "single-party" system of government tends to create a new form of special privilege dependent upon party allegiance. But in all systems, a job analysis will reveal the need for continuous education after entrance if there is to be an adequate supply of recruits for the higher directive and technical positions. Hence, the questions of "in-service" training, of educational leave and the recruitment through promotion and from outside the service are as much the subject of discussion and experiment as the older question of "pre-entry" training. At this point the interest of students of public administration turns to developments in education and psychology generally as well as to experience in industry and commerce.

The Budget.—The outstanding instrument whereby the total program of a government for a given period of time is set forth by organization unit, types of expenditure and in other detail is the budget. In most states (notably Great Britain, which contributed most to its development as an important tool of government) the budget originates in the executive departments in the form of estimates of proposed expenditures and the revenues to cover them, is submitted to the legislature for investigation, amendment and legal authorization and is then administered by the budget and other finance agencies. The budget process ends with an audit to determine whether expenditures have been properly based upon the legal authorization—an audit frequently made by an agency of the legislature, or otherwise independent of the administrative chiefs. The budget as authorized by the lawmaking process is

thus inevitably the total plan for all the activities of the government for the next fiscal period (generally a year), including the provision for personnel and materials. The long evolution of representative government has centred largely in the development of a good budget system, including "the control of the purse strings" by the elected representatives of the people; that is, the submission to them by the executive (usually in name, at least, by the crown) of the proposals for expenditure, taxation and loans and the scrutiny and amendment, acceptance or rejection of these by the representatives, sometimes with the aim and result of forcing administrative chiefs and policy advisers from office. The cabinet system, whereby the chief executive officials must possess the support of the majority of the legislature, thus had its origins; while the importance of legislative control over expenditure, and of the appropriation process, is illustrated also by provisions concerning them in the constitution of the United States and in the development of government everywhere.

The Planning Process.—The function of cabinets and chief executives as well as the heads of large departments in the preparation of policy for submission to the legislative authority became complex and difficult with the widening and interdependence of the functions of government. Thus, in a metropolitan area the design of streets and highways, water supply, parks and schools is dependent upon population, industrial, commercial and technological trends as well as changes in the ideas held by citizens as to standards of living. As a result, the usual budget processes are sometimes supplemented by special staff agencies for investigation and analysis, or by regular and continuing agencies to which the term planning is applied. Planning as an inherent need in the structure and process of administration was diagnosed and recommended by Frederick W. Taylor in his pioneer work in scientific management, although, as noted above, it has been called into existence in some form, as in military affairs, wherever thought has been applied to the problem of the improved preparation of programs.

The economic policies adopted by the early modern states caused the rise of career civil services and methods of training for them. A similar increase in collective services, whether in the U.S.S.R. with its elaborate central, regional and local programs of state action, or a region of sparse population requiring long-time land policies in the United States, or a great urban agglomeration such as London, Bombay or New York, made desirable and necessary the establishing of planning agencies. Their function is to gather and analyze data concerning the problems of the political organisms they serve and to submit reports on their studies to the political chiefs, the legislatures and the electorate. Sometimes these agencies are also given some operating responsibility and power. Thus, they may be given the enforcement of controls over land use or authority to determine priorities in the allocation of resources to projects. Whether such planning agencies should be exclusively research and advisory in their functions or should have in addition operating functions and powers is a subject of controversy among students of administration. It is agreed, however, that there should be close and sympathetic working relations and an interchange of personnel between them and the budget and other general staff and auxiliary services and the substantive departments.

It may again be stressed that the budget should reflect, as the most comprehensive record of operations proposed for the next fiscal period, the result of the planning process as registered in the working and financial program which the chief executive and his associates are responsibly proposing to the highest lawmaking body of the jurisdiction. Thus, the estimates which are proposed will presumably be supported and justified by the analyzed data. Viewed in this light the planning process in administration is not, as sometimes argued, in opposition to legislative authority but essential to it. A legislature, in fact, may rightly demand that such preliminary collection and analysis of data be undertaken by the executive to ensure a better preparation of proposals placed before it. The use of the fiscal policy of a government to affect general economic conditions by its influence on investment and employment increases the need for careful planning of the estimates.

Internal Operation.—The directive, general staff and auxiliary agencies exist to serve the substantive or operating departments, and it is through them that the functions of a political system are applied. In these basic substantive departments there is a division of labour reflected in an organization of units whose heads are related in some line of responsibility and power. The system may be recorded on organization charts and in standard specifications for every position whereby the duties, qualifications, rates of payment and official titles are set forth. The relation of the different levels, the flow of correspondence, reports, memoranda and dockets of official business and the arrangements for conference between units (bureaus, divisions, sections, branches, regional offices, etc.) may also be guided by written and official codes of procedure. The procedure to be followed in relations with the public generally by correspondence, interview, investigation or inspection, or hearings of an informal or formal type, tends to become standardized and codified. This results in a standardizing of practice that leads to charges of red tape, bureaucracy and the stultifying of initiative. A failure to regularize procedures, however, leads to criticisms of unfairness, capriciousness and abuse of power and an invitation to corruption. The interests affected by the function administered are generally organized in economic or professional associations. Sometimes representatives of these interests are brought into official participation in the administrative process through committees advisory to the agency or committees given some power of administering the program for which the agency is ultimately responsible. At its extreme, such a system might be termed "the corporative state" so much discussed in political theory in recent decades, although never actually embodied in any completeness.

Among the groups involved in the administrative process with some special interest or emphasis of their own are various organizations of the civil servants. Since the number of civil servants in a modern state may be great, collective action in the effort to affect rates of pay and conditions of employment generally developed despite opposition. In some systems, a regular procedure was established (as notably in the "Whitley councils" in the British civil service) for consultation between the directive and personnel officials and the representatives of the civil service organizations.

Thus, the maintenance of some balance in modern administration between the interests and attitudes of legislatures, parties, executive leaders, auxiliary service agencies, interest groups affected and the civil servants themselves is no easy task. The systems appear sprawling, cumbersome and unwieldy and too far removed from the situation from which the call for governmental action originated. Internal operation is complicated further by the relating of decisions taken at the centre to the varied conditions in the field.

The problem of clarifying and explaining the complex task of a department led to increased interest in methods of reporting. Experiments in the use not only of printed and illustrated reports but of the motion picture, the radio, television and direct face-to-face discussion and conference were undertaken. Legislatures are inclined to oppose these on grounds that they may become an alternative to the party system as a means of consulting public opinion and may stimulate public pressure for legislation favourable to the agency employing them.

The problems of internal operation in public administration are in many ways akin to or identical with those in other social institutions, including industry and commerce. The comparative study of institutions, including the relation of individuals in the smaller face-to-face groups, brought scholars and administrators together from many fields to share experience and plan and conduct research. Psychologists, personnel managers, anthropologists, sociologists and many other workers find a common field in what is given various names, such as social relations, human relations or the study of the human group. A special challenge was raised by growth of international programs and agencies in which the problems of a substantive field such as health are complicated by the need for co-operation by peoples of different cultures. The training of administrative personnel for such programs began to

reflect the new emphasis on human relations, and also the area or regional studies whose origins may be found long ago in the policies of missionary societies and colonial offices, as well as in World Wars I and II.

DECENTRALIZATION AND DEVOLUTION

Whenever the size in area and population of the jurisdiction served by an administrative system is large, the adjustment of general policies and standards to varied local or otherwise specialized circumstances constitutes a major problem. If too great freedom is given to officials to adjust standards to the particular instance, effective general legislation becomes difficult or impossible, and programs may get distorted and special interests may injure the general good. Partisan, sectional, factional or other special favours and corruption may follow. And yet the particular knowledge of the persons whose life work is in an industry, or is concerned with a commodity or profession, or with a particular region or locality, should be employed if a policy is to be wisely administered. The states of the world have in all times, from ancient China or the Roman empire to the present, attempted to meet this problem either by leaving or giving some measure of local self-government to local areas, or by creating regional units in their central administrative agencies to which some discretionary powers for making decisions within the general rule for problems arising within the area are given.

A variant of the same principle is the assigning of powers for the administration of a statute or general policy of the state to a professional, commercial or industrial association or representatives of such interests. Thus, we may find, as in the Germany of the Weimar republic, not only *Länder* or member states within the Reich but local units within them and also an economic council. Similarly, in Great Britain, which we ordinarily think of as a unitary or relatively centralized state, there are county councils, rural district councils, boroughs and also boards possessing statutory powers in the steel industry or dealing with a commodity such as milk or bacon. In the United States the same problem of relating general policies to the particular situation confronted the constitution makers in 1787, resulting in a federal system, but persists to the present and indeed becomes more complicated as new units such as soil-conservation districts or local housing authorities are created with direct relations with national agencies.

The grant or taking of power by economic groups was advocated perhaps more strongly at about the time of World War I, and a political theory designated "pluralism" or "functionalism" had a period of success. It was indeed supposed to have been reflected in the doctrines of the Russian bolsheviks and the fascists in Italy, as well as in the creation of economic councils in France and Germany. Probably local circumstances and situations in the latter two states, just as in the establishment of the National Recovery administration in the United States, with its industrial codes, had a much greater importance, while the Russian and Italian systems quickly revealed themselves as highly centralized single-party controlled governments struggling to secure and retain power and therefore in no position to yield power to regional or commodity or other groups except as forced by circumstances.

The point is, however, that circumstances (*i.e.*, the increasingly complex nature of the activities that go to make up modern economy, the strong pull of neighbourhood and region and all kinds of provincialisms and the necessity to achieve political as well as administrative success for policies) do press for the adjustment of general policies to particular situations and do require the consultation at least by administrators with persons and organizations affected by those policies. It is characteristic of modern legislation affecting industry in some states, for example, that councils on which employers and employees, or members of a profession, are represented, participate in drafting rules and regulations under the act.

Relations of a national or central authority with provincial and local governments are made more complicated by the rise of metropolitan cities that spread over several separate political jurisdictions, the inequality of tax resources of local units, the pressure for national minimum standards of public services and the

interdependence of economies. A partial answer to these conditions is found in the grants distributed from national funds to local units on condition of meeting certain required standards, with resulting inspection from the centre, generally entitled "grants-in-aid," and in the employment of officials of one level of government for enforcing the laws of another. The relation of levels of government remains, however, as one of the most difficult and perplexing problems of public administration.

CONTROLS AND STANDARDS

Obviously public administration is certain to be subjected to criticism because the objectives sought are disliked or because the methods employed are viewed as unjust or inefficient or corrupt. Over the centuries various devices for its control have evolved. These efforts are designed to confine it to the political objectives for which a particular administration is established, which we may call political control; to ensure economy and efficiency, which we may call executive control; or to ensure observance of the accepted rules of fair conduct as understood by the particular society to apply to the relation of officials with the public, which we may call judicial control. All these necessarily intermingle, and broadly speaking, with the rise of representative government, a somewhat stronger emphasis inevitably was placed in most states upon political control. This is exercised through making the chiefs of administration politically responsible either to the legislature or to the electorate by some form of popular election.

Probably the most famous example of the evolution of political control is the wresting of power from the king and its allocation to a committee of party leaders representing a majority of the House of Commons in Great Britain. This system, called "cabinet" or "parliamentary" government, served as a model for many other states to follow (with varying degrees of success). The U.S. "presidential" or "congressional" system makes the chief executive responsible to the electorate. Both systems, however, operate through parties; and at times the British prime minister takes on presidential attributes, and the U.S. president similarly at times plays a role in relation to Congress somewhat akin to that of the prime minister in relation to the House of Commons.

The more detailed devices of party and legislative control vary greatly; but most legislatures employ committee investigations of administration, scrutiny of budget estimates, the control over expenditure and audit and frequently the questioning of executive chiefs on the floor as well as in committee. These matters are usually topics of discussion at meetings of the Interparliamentary Union, the conference of delegates from the legislative bodies of the states of the world.

The struggle of legislatures first for independence of the monarchy and later for supremacy is paralleled historically in many states by a similar effort of the courts for independence; and in some states, notably the United States, the system of written constitutions and a federal distribution of powers has been the basis upon which has been constructed the exercise of judicial review not only of the acts of officials but of the constitutionality of the statutes whereby the officials may have justified their actions.

In many states, notably those influenced strongly by the traditions and precedents of the Roman law, a series of special courts evolved in which controversies involving official acts of civil servants are adjudicated, and the resulting case law, as in France, constitutes an important part of the public law. Administrative law is thus everywhere a branch of public and constitutional law that grows in importance as the extent and complexity of the functions of government increase. Questions of the competence of the authority, the adequacy and justice of the procedure, the extent of the grant of discretionary power, the adequacy of the evidence in support of the administrator's action and the finality of the administrative decision are typical issues. The study of comparative government, and in particular of comparative jurisprudence and administration, is resulting in a greater familiarity on the part of scholars and of some practitioners with the similarities between different systems and a tendency to discover devices in one system that may usefully be adopted in another. Many precedents and theories framed long ago during the struggles with

monarchy are being reappraised in the light of the contemporary complexities of administration.

While legislative, executive and judicial controls are of basic importance, it should not be forgotten that in the daily life of the administrator his own knowledge, character and sense of personal and professional responsibility, constituting a series of inner standards and checks, are probably more immediately and intimately influential. Hence, the rise of professional organizations, of research, of in-service training, of journals devoted to administrative questions have increasing importance and constitute a professional control which has operated, indeed, at times in all societies.

The increasing participation of citizens in public administration through advisory committees, and their sharing in the exercise of some of the discretionary power in rule making, and the necessity for many types of administration of winning the understanding if not the active support of the citizen, is another less recognized but important control over public administration. Many statutes and programs involve matters touching intimately the lives of great numbers of citizens; it is impossible to enforce them (as, for example, systems of social insurance or of highway safety or disease prevention) without extensive efforts to acquaint citizens with them. But in that process, the official is often educated himself as to attitudes, habits, capacities and problems of those whom he is supposed to serve; he is probably less concerned with possible legislative, judicial or even higher executive action regarding his work than with the people and problems immediately at hand. In this sense, we may consider administration as moving into a stage in which a two-way educative process is discernible; and while it may seem a far cry from the edicts of ancient rulers, one suspects that even they, too, had sometimes to consider how far they could go with subjects unaware of or opposed to their aims and measures.

PUBLICANI, the name given in ancient Rome to public contractors, who either undertook (on receipt of a fixed sum from the treasury) to erect or maintain public buildings or supply armies overseas, or paid a fixed sum to the treasury for the right to exploit state mines, quarries, salt pans, or forests, or to collect certain taxes. The general principle was that only those state assets whose revenue was fluctuating and uncertain were farmed to *publicani*; thus tithes and customs were farmed, but in provinces where the tax was a fixed tribute, it was directly collected from the provincial communities by the quaestors. With the growth of the empire the provincial tithes became the most important contracts undertaken by the *publicani*. The system was well established by the end of the 3rd century B.C. At Rome the contracts were let by auction by the censors, and thus ran for five years; in some provinces, such as Sicily, they were let annually by the praetor. Payment was made in arrears, but the *publicani* had to furnish guarantors (*praedes*) and securities (*praedia*), and since many of the contracts involved very large sums they commonly formed partnerships or companies (*societates publicanorum*). The companies were headed by *magistri* at Rome and *promagistri* in the provinces, and employed large staffs (*operae*), free and slave, as accountants, collectors, etc. They organized their own postal service, which was often used by the provincial governors. They also acted as bankers to the state, making payments in the provinces on behalf of the Roman treasury.

Since senators were legally debarred (probably by the *lex Claudia* of 218 B.C.) from undertaking public contracts, the business fell into the hands of the richest nonsenators, the equestrian

order (see *EQUITES*). Their interests often clashed with those of the state, as represented by the censors and the senate; in 169 B.C., for instance, the censors excluded past holders of contracts from the auction on the ground that they formed a ring to keep the bidding down, and the *publicani* appealed to the tribunes of the plebs, who prosecuted and nearly convicted the censors. From 122 B.C., when equestrians became jurors in the court of extortion, the *publicani* acquired a whip hand over provincial governors, since they could condemn governors who restrained their operations, and most governors found it wise to connive at their malpractices, in which case the jurors would turn a blind eye to the governor's extortion. The provincials suffered as a result, being compelled to accept gross overestimates of the amount of tax due, and to pay extortionate interest on arrears.

Under the early empire the amount of business handled by the *publicani* was greatly reduced, as provincial tithes were abolished and fixed tribute substituted. They continued, however, to exploit mines and collect customs, and were employed to collect the new inheritance tax (*vicesima hereditatum*). They were more closely controlled, being supervised by imperial procurators, and the margin of profit was gradually so reduced that bidders did not come forward.

The government responded by compelling existing contractors to carry on under the same terms—an abuse condemned by Hadrian—or by assigning contracts compulsorily to wealthy men. In many cases the farming system was abandoned, and the tax collected directly by the procurator. Under a law of Constantine the customs were still farmed, but the system was little used in the later empire.

PUBLIC DOMAIN. Broadly defined, this term denotes the ownership of natural resources by the people of a society generally as distinguished from ownership by particular persons or groups. This broad definition encompasses a wide variety of public ownership possibilities. Thus an Indian tribe that claims exclusive hunting and fishing rights in a particular area, but permits any and all of its own people to hunt and fish therein without restriction, is administering a public domain. So too is a modern Communist state that manages the use of economic resources by means of a centralized planning machinery. And even a feudal society in which all land is held of the king is in effect maintaining its economic organization within a public domain framework. The phrase "in the public domain" is also used to denote literary works or inventions not protected by a copyright or patent.

As the term is most commonly used, it is thought of as referring to the ownership or disposition of natural resources by the government in a society in which private property is also an important institution. Indeed, the concept of public domain could hardly have come to occupy the position it does if it did not suggest a contrast—and perhaps even a conflict—with the concept of private domain. Certainly no experience anywhere in the world illustrates this relationship more concretely than that of the United States.

Several factors have contributed to the sharpness of this contrast in the United States. One is a decision made early in the nation's history that, outside the original 13 colonies, land would be publicly owned before it became privately owned. The converse of this idea was the equally early and definitive policy that public ownership status would, for the most part, be a way station on the road to private ownership. When these two decisions are considered together they largely explain why so much of American history has consisted of a vigorous effort to add to the public domain and an equally vigorous effort to alienate that domain.

It is also necessary to add one more consideration in explaining why the public domain has consistently been a vital dimension of U.S. political life. Because a vast area was originally put into the hands of the federal government (the Floridas and all the territory within what is now the United States that lies west of the Mississippi River, with the single exception of Texas), it was only natural for that government to endeavour to further particular public policies in the process of disposing of these resources. It

was only to be expected that, in a private property society, whatever public policies were selected for implementation in this way would encounter some opposition.

When, for example, the central government, immediately after the Constitution was ratified, decided to use the public lands as a source of quick and easy revenue, there were those who bitterly complained that this policy favoured speculators and wealthy farmers at the expense of the landless masses. Later when this policy was reversed during the Civil War, and a Homestead Act passed which gave land to settlers in 160-ac. lots, every conceivable effort was made by larger operators to keep bona fide homesteading to the barest minimum. When simultaneously a broad attempt was made to push railroad expansion by means of a system of land grants, farmers were quick to point out that the railroads were thereby being given much of the most desirable land—that nearest a railroad. And, strange as it may seem, public land policy was for many years closely related to the tariff question because revenue from the sale of public land proportionately weakened the argument for higher import duties.

These instances suggest only a few of the many public policy uses to which the public domain has been put. It has been used to pay men who have served their country by fighting for it—especially after the American Revolution when the soldiers could not have been paid in cash in any event. Even before the advent of the railroads some of the proceeds from the sale of public lands were earmarked for improving the nation's transportation network. And another land grant system was inaugurated to assist the states in developing facilities for higher education. (See LAND-GRANT COLLEGES AND UNIVERSITIES.)

More recently the United States has experimented with policies not based on rapid and complete alienation of the public domain. Before the end of the 19th century it was decided that a policy of reserving some mineral rights would be in the public interest. After World War II a retroactive claim on minerals in the fission-fusion family was asserted. Nonalienation has also become a significant element in the government's approach to the remaining public domain. One key instance here is land containing oil. But perhaps the primary reason for nonalienation is conservation of wildlife, of natural beauty, of soil and forests.

PUBLIC ENTERPRISE, an undertaking that is owned by a national, state (or provincial), or local government, supplies services or goods at a price, and is operated on a more or less self-supporting basis. Such enterprises may also be international, interstate, or intermunicipal in character, i.e., owned and operated jointly by two or more national, state, or local governments. They may be operated by a government directly through one of its administrative departments or indirectly through a specially created semiautonomous corporate or other body, or through a company of which the government is the sole or practically the sole shareholder. A company in which the government owns only a portion of the stock, the other portion being owned by private individuals or groups, is generally designated as a "mixed" enterprise, rather than as a public enterprise proper. Social insurance systems and government employee retirement funds are not deemed to be public enterprises, inasmuch as membership in them is generally obligatory and their services are not sold.

Main Characteristics.—Public enterprises have certain characteristics in common with tax-supported administrative services: they are organized and operated for public benefit and they sometimes cater to the same public needs, though in a different manner. Thus, for example, they are often set up for the construction and operation of express highways, bridges, canals, and tunnels which might otherwise have been constructed and operated as free facilities financed from general taxation or tax-supported bond issues. But public enterprises also differ from tax-supported administrative services in several respects. First, they are concerned with the supply of only such services or products as are divisible into specific units for which specific charges can be made to the in-

dividuals wishing to acquire them. Public enterprises can never be set up to supply services or products which confer common benefits for all and are not divisible into such units. Thus, public enterprises can be organized for the supply of postal, telegraph, telephone, broadcasting, railway, seaway, and airway services and for the supply of electricity or gas, but not for the supply of national defense, protection of life, property, and health, social welfare services, and the regulation of business. Secondly, unlike tax-supported administrative services, public enterprises raise their own revenues and sometimes even their own capital funds; they are often allowed to dispose of their funds as they deem best, subject only to the general directives contained in the laws under which they are established or in the broad policy statements enunciated by the government; and their directors, managers, and other personnel are often appointed without regard to either politics or civil service regulations.

On the other hand, public enterprises differ basically from most private enterprises in their motivations and their modes of operation. First of all, they are operated for public benefit rather than private profit. Secondly, in capitalistic or free enterprise economies their prices are generally set at levels merely sufficient to cover their costs of operation, and not, as in private enterprises, high enough to earn a profit. Though their aim most frequently is to furnish services or goods at the lowest possible prices, there may occasionally be involved a subsidiary purpose of earning a profit for the government, thus sparing the necessity for levying additional taxes. Thus, for example, if the services of municipally owned electric light and gas plants are sold not only to the consumers of the owning locality but also to those of neighbouring communities, the locality is able, through the profits earned on such extraterritorial sales, to shift some of the support of its government to the shoulders of the neighbouring communities. In national fiscal monopolies prices are always set considerably above costs in order to earn a net profit for the government. Thus, in various ways public enterprises occupy a midway position between tax-supported public administrative services and private business undertakings, and combine some features of each.

History.—The development of public enterprises during the past three centuries or so can be divided into four periods. The first period began in the middle of the 17th century and extended into the end of the 18th, during which time national public enterprises were generally limited to the operation of the public domain (consisting mainly of state forests), the newly established national postal offices, and one or two fiscal monopolies surviving from the older times, such as the old and rather infamous salt monopolies. Local public enterprises during the period were limited to the operation of municipal markets, docks, and ferries. In general, public enterprises were not clearly differentiated from regular administrative services and were usually administered in about the same manner.

The second period, which began about 1800 and ended with the outbreak of World War I, saw a rapid industrial development and urbanization in the Western world. During that period national and state public enterprises were established for the construction and operation of canals, railroads, telegraph and telephone services, and port facilities, and for the operation of new types of fiscal monopolies, embracing principally the manufacture or distribution of tobacco products and alcoholic beverages. Municipal enterprises were established in the larger cities for the supply of water, gas, and electric light, and for street railway and underground rapid transit services. During this period, too, public enterprises came to be more clearly differentiated from ordinary administrative services and to be organized in a way better suited to their peculiar nature.

The third period began with the outbreak of World War I and ended with the outbreak of World War II. During that period, national and state enterprises multiplied throughout the Western world under the influence of the political, social, and economic forces unleashed by the war and, a decade or so later, by the depressions of the 1930s. The effective prosecution of the war had necessitated in most of the warring countries the nationalization of some of their industries at least for a time, thereby tending

for many years to make people regard nationalization with less awe than before. (See also NATIONALIZATION.) Moreover, in those countries in which particularly great devastations of industrial plants, homes, and other properties had taken place, the tendency toward nationalization of industry and transport was stimulated because the work of reconstruction required extensive participation by the national government. In many instances the industrial enterprises that had been reestablished by the government were not returned to their former private owners and continued to operate as nationalized enterprises. Moreover, the political and social revolutions which broke out during and after the war in the Soviet Union, Turkey, and Italy and the revolution in Mexico (which started earlier but extended well into the 1920s and 1930s) not only brought about either complete or partial nationalization of industry in these countries but also exerted a powerful influence in the direction of greater extension of public ownership in other countries.

These tendencies toward public ownership were compounded during the world depressions of the 1930s. In the United States, France, and several other countries national governments were compelled to extend various forms of emergency aid to bankrupt business firms, farmers, homeowners, and unemployed workers, and to establish permanent financial institutions and other undertakings to ensure stability and continued growth of the economy.

The fourth period began with the outbreak of World War II and is still continuing. During it public ownership was expanded even more rapidly than before, affecting many more countries and many more industries in each of them. This was a natural consequence of the greater magnitude of World War II and of its far-reaching and lasting political, social, and economic effects. In a number of industrially advanced countries that had been directly involved in the war or otherwise deeply affected by it, some additional industries were nationalized after the war under the pressure of various forces. Moreover, during this period in a number of underdeveloped countries which had become imbued with a desire to achieve rapid industrial development and a higher standard of living for their people, the governments established to that end industrial undertakings, often with the aid of funds borrowed from abroad. Finally, Communism during this period won several more adherents among the nations of the world, resulting in the complete nationalization of their industries.

REASONS FOR ESTABLISHMENT

As the foregoing historical summary indicates, the reasons for the establishment of public enterprises are varied. Some are economic, fiscal, or administrative; others are broadly social, ideological, and political. Economic, fiscal, and administrative considerations were responsible for the establishment of most public enterprises during the 19th century and the beginning of the 20th century; they still play an important role in many countries, including the United States. Public enterprises established for these reasons have not been designed to change the order of society. The second category of reasons, on the other hand, has come to play an important role in the organization of public enterprises since World War I and has tended to transform the capitalist or free enterprise society into either a semi-socialist economy or a completely socialist or communist economy.

Economic.—The economic reasons are generally concrete and deal with specific institutions. If a need has developed in the society for new facilities, services, or products and if private enterprises appear unwilling, or incapable, to undertake to supply these facilities, services, or products, the government has no alternative but to undertake to supply them itself. Similarly, if, after having organized such facilities and operated them for a while, private enterprises appear unable to continue to operate them in a manner satisfactory to the public and profitable to themselves, the government is impelled to purchase or otherwise take over their properties and operate them itself (generally with the hope that by reorganizing and coordinating the facilities it might be able to operate them more efficiently and economically). In the 17th, 18th, and early 19th centuries, for example, the inability of private enterprises to provide satisfactory mail service forced national

governments everywhere to establish them themselves. In many countries the national governments (or their states or provinces) had to construct and operate canals and railways from the very outset or had to take their operation out of private hands at later times. The same thing happened in most countries in the case of telegraph, telephone, and broadcasting services. Even coal mining had to be taken over from private enterprises in many countries in the 20th century because the industry could no longer be operated by private enterprises economically and efficiently and with profit to themselves. In every such instance, the government's entrance into the field was dictated by the economic realities of the situation and not by shifts in ideology or by any play of politics.

Administrative.—Sometimes, however, administrative and public considerations reinforce the economic ones in prompting the establishment of a public enterprise. For example, the construction and operation of railroad lines in some cases was of such strategic importance for national defense, but not likely to be economically profitable, that it had to be undertaken by the national government. In other cases a wholly different set of economic circumstances has impelled the national government to take over a given private enterprise. Thus, for example, when a large private enterprise has developed into a monopoly charging exorbitant prices for its services or products and defying government regulation, its acquisition by the government and its operation as a public enterprise is advocated as one way to deal with the situation. Another way is for the government to establish its own enterprise in competition with the private enterprise, thereby breaking the latter's monopoly and forcing it to cut its prices.

Fiscal.—Fiscal reasons for establishing public enterprises are also specific and concrete. Thus a government may terminate private operation in a certain field of economic activity and establish therein its own enterprise as a monopoly, because that monopoly can then charge high prices for its services and bring in a net revenue larger than any tax imposed by it on the private enterprise operating in that field could possibly bring in. Occasionally too, a government converts a tax-supported administrative service into a service-charging public enterprise for fiscal reasons. By so doing, it relieves its budget of an additional burden.

Ideological.—Broad ideological, political, and social reasons for establishing public enterprises often involve a desire for the reconstruction of the political, social, and economic order of the society. Sometimes the aim may be to reconstruct it on a supposedly more equalitarian plan; sometimes, conversely, the object may be to reconstruct it along a more authoritarian and militantly nationalistic plan. In other instances, the aim of the political program involving the establishment of some public enterprises is not so much to change the social order as to accelerate the industrial development of the country as a means of quickly improving the economic welfare of the people. In either case, a sweeping and more or less coordinated establishment of public enterprises takes place in the country.

Examples of sweeping nationalizations of industry for broadly ideological, political, and social reasons are afforded by the revolutions of recent decades which have transformed Russia, most of eastern Europe, China, and other countries into communist societies. Examples of politically and ideologically inspired nationalizations tending to transform a national economy into one of semi-socialist or mixed type are found in the programs effected in Australia under the influence of the Labor Party in the 1920s and 1930s, in New Zealand under the Labour government (1935-49), in Mexico in the 1920s and 1930s, in France after the end of the German occupation during World War II, in the United Kingdom under the Labour government (1945-50), and in India under Nehru's administration after that country's achievement of political independence. The aims of the nationalization program of the British Labour Party, only part of which was achieved during the foregoing brief period when it was in power, included the removal of the concentration of economic power from private hands in the interest of a more democratic society, increase in the efficiency of industry through better coordination, assurance

of greater worker participation in the management of industry, and stabilization of employment.

The sweeping nationalization of finance and industry effected in Italy under Mussolini's Fascist regime, which was designed to achieve economic self-sufficiency for the country and to enhance its military power, was in a class by itself. So, too, was the nationalization of some industries in Germany under Hitler, the aim of which was to mobilize the nation for an aggressive war. Quite different were the attempts made by the Italian government after the liquidation of the Fascist regime to democratize the country's control over the nationalized industries. Finally, the sweeping nationalization of industry in Turkey under Kemal Atatürk in the 1920s and 1930s exemplified an effort to accelerate the country's industrial development rather than to reconstruct its social structure along more equalitarian lines.

Importance.—It is very difficult to measure the relative importance of the public enterprises in various national economies. The proportion of the country's total labour force employed by its public enterprises, even if computed accurately, is not an accurate measure of their relative importance. For one thing, it ignores the qualitative importance of the industries operating under public ownership, and the impact they have on the operations of the whole economy. The proportion of national income or gross national product originating in public enterprises is not an ideal measure of their relative importance. The economic importance of the nationalization of banking, for example, can hardly be measured by the small number of persons employed in banking or by the income produced in banking.

The portion of the labour force employed in public enterprises in the capitalistic or mixed economies is only 9 to 10% in the United Kingdom and France, 6 to 8% in Italy, Australia, New Zealand, and Sweden, and less than 2% in the United States. Such figures are not impressive if taken by themselves. However, when taken in conjunction with a listing of the types of economic activity covered by public enterprises, they become more meaningful.

Among the industrially advanced nations with capitalistic and mixed economies, the widest range of economic activity covered by public enterprise prevails in the United Kingdom, France, Italy, Sweden, Australia, and New Zealand. In addition to the post offices, public enterprises in these countries operate other great utilities such as telegraph, telephone, broadcasting, railway, electric light and power services, large segments of seaway transport, practically all air transport, all coal mining, and substantial segments of financial services. In some of them, public enterprises also operate road haulage, life insurance, some types of housing, some metal mines, steel and iron plants, automobile factories, and shipbuilding. In Sweden even a chain of restaurants is publicly operated. A somewhat narrower range of coverage of both the basic utilities and industries generally prevails in the Federal Republic of Germany, Canada, and Japan. The narrowest is found in the United States where, with a few exceptions such as the Alaskan Railway and the Tennessee Valley Authority, railways, telegraph, telephone, broadcasting, and most of the gas and electric light and power services are still under private ownership and operation.

FORMS OF ORGANIZATION

Centralized or Decentralized Organization.—One of the issues in the organization of public enterprises relates to the extent to which they should be set up as large units owned by the central government and serving the entire nation, or as small units serving regions or local communities and owned by state, provincial, or local governments. To a large extent, this issue takes care of itself through the natural accommodation of the public enterprises to the character of the services in question. Thus, to meet properly the public needs, the public postal, telegraph, telephone, broadcasting, railway, seaway, air transport, and certain types of financial services are generally centralized and operated nationally. Road transport, coal mining, and hydro-electric power development are in some instances organized as national undertakings and in others as regional or local enter-

prises. The supply of strictly urban facilities, such as water, public housing, street railway, bus, and underground rapid transit services are usually municipal undertakings. Harbour and airport facilities are in some countries carried on as national undertakings and in others as nationally subsidized local enterprises.

Degree of Autonomy.—Another important issue in the organization of public enterprises relates to the extent to which, because of their public purposes, they should be controlled by the central government or, because of the business character of their operations, they should be given freedom to make their own decisions and to act upon them. This issue arises in the determination of such matters as the manner in which their chief officers should be appointed and the conditions under which they should hold office; the extent to which they should be required to report to the legislative and executive organs of the government and to take directives from them; and the degree, if any, to which they should depend on the government for the supply of their capital and have their budgets controlled by it, have the right to fix the pay of their personnel, determine charges, and retain and dispose of profits.

The arrangements which may be adopted for the management of public enterprises in these and other respects may range from controls that are almost as tight as those exerted by the government over its regular administrative services to those that are as loose as those applied by it to private businesses. In any event, they are closely interlocked with the type of legal organization under which a public enterprise is set up. There are four main types of such organizations: the administrative department; the so-called trading agency; the company; and the public corporation or "authority." The following paragraphs describe each of them briefly, giving attention to the degree of government control or autonomy generally found with each type.

The Administrative Department.—The earliest public enterprises were organized as regular administrative departments, and many are still so organized in most countries. This is particularly true of the post office and the telegraph and telephone services. Under this type of organization the head of the public enterprise is appointed by the legislature or by the chief executive as is the head of any other administrative department. The budget of the enterprise is often subject to the same control by the treasury or other general budgetary agency of the government as that of any other department. Frequently, no consistent attempt is made under this type of organization to relate closely the charges made by the enterprise for its services to the costs of rendering them and to relate the income of the enterprise to its outgo. Sometimes the receipts of the enterprise from its charges are paid into the general fund and its expenditures are paid out of it without any comparisons being made of the relation of the one to the other. In other cases a contrary arrangement is followed; the receipts are paid into a special fund and the expenditures are made from that fund to the extent that the receipts are sufficient to cover them. If there is an excess of receipts over expenditures it is turned over to the general fund; if expenditures exceed receipts the deficit in the special fund is taken care of by an appropriation from the general fund.

Trading Agency.—The so-called trading agency is a type of public enterprise organization that originated in Sweden. A modification of the administrative department type, it differs from it in two main respects: its heads are nonpolitical persons appointed by the King-in-Council and bearing no ministerial political responsibilities; and it allows the enterprise somewhat greater freedom of operation than is permitted under the other plan. For example, the enterprise may be allowed to retain some of its profits. Its personnel, like that of an administrative department, however, are under civil service. This type of organization is used in Sweden for the management of the largest national enterprises, such as the postal, telegraph, telephone, broadcasting, railway, air transport, electric power services, and forestry.

Company.—The company type of public enterprise organization has its origin in the private companies that used to operate the particular businesses before their stock was purchased by the government. In taking over a given private company the gov-

ernment would retain its legal form, but, through its ownership of all or nearly all the shares and election of all the directors, it would change the internal organization, nature of managerial personnel, policies, and modes of operation. The company type of organization is used also for setting up wholly new undertakings not formerly owned by any private group. Its advantage lies in its flexibility and in the freedom which it affords to the public enterprise to manage its affairs without interference from the treasury or from civil service regulations. It has one major disadvantage, however, from a public point of view: the absence of public accountability. The company type of organization is quite common in France and in Italy. In Sweden it is used mainly for the operation of small public enterprises set up in competition with private enterprises.

Public Corporation.—The public corporation or "authority" is the newest type of organization of public enterprises and, by consensus, appears to be the most satisfactory. (See GOVERNMENT CORPORATIONS.) Developed first in the fullest form in England in the case of the Port of London Authority in 1908 and next in the United States in the case of the Port of New York Authority in 1921, it spread rapidly in those two countries and was copied by a great many other countries. The public corporation is set up as a semiautonomous body subject to some degree of public accountability. Its specific features are generally set forth in the special statute which creates it. Each public corporation is supposed to be so organized as to enable it to operate efficiently, economically, and responsibly in the field assigned to it.

William A. Robson in his *Nationalized Industry and Public Ownership* (1960) observed that in Great Britain two factors provided the original impetus for the creation of public corporations; one was the desire to free public enterprises from parliamentary supervision over management and the other was to free them from Treasury control over their personnel and finances. He listed five requisites for the proper organization of a public corporation: freedom from parliamentary or other legislative inquiry into the management of the corporation as distinct from its policy; disinterestedness; operation outside the civil service; independence, i.e., divorcement from the general budget (which does not necessarily exclude the supply of capital funds or operating subsidies to the enterprise from the public treasury); and that the chairman and board members of a corporation be appointed for a fixed term of years, thus ensuring their independence from political control.

In Britain, the public corporation has been represented by such bodies as the Central Electricity Generating Board and Electricity Council (both formed in 1957), Bank of England (1936; reorganized in 1946), National Coal Board (1946), and the Transport Commission (1947). In the United States, it is exemplified by the Tennessee Valley Authority (1933), Export-Import Bank (1934), Port of New York Authority (1921), and the New York State Thruway Authority (1950).

Mixed Private-Public Enterprises.—Mixed enterprises owned partly by the state and partly by private interests are prevalent in France, Italy, Sweden, Brazil, and in some other countries. They have their origin in the acquisition by the state of some or most of the stock of private companies. They retain the legal form of privately owned companies but in their internal organization and in their operations, i.e., in the composition of their boards of directors and in the nature of the policies pursued by them, the mixed corporations reflect to some degree their partial public ownership. Where the proportion of the shares owned in the company by the state is very small (as in the case of the Hispano-Suiza Company in France, where it amounts to only 4%), the enterprise may be deemed to be merely a subsidized private enterprise, rather than a mixed enterprise proper. But where the proportion of the public and private holdings is about evenly divided, the enterprise deserves to be designated a mixed undertaking. There is much controversy regarding the merits and demerits of the mixed type. Criticisms are directed especially against those mixed enterprises in which the state owns a majority of the stock. In analyzing the experience of this

type of enterprise in France, Maurice Byé concluded that it differs from genuine governmental undertakings only "by being camouflaged with the trappings of private business, and linked to the state budget by agreements that make the state responsible for unlimited deficits." In the U.S. the establishment of mixed corporations by state and local governments is prohibited in most states by state constitutions. The federal Constitution does not forbid their establishment by the federal government.

Criteria of Soundness and Effectiveness.—The criterion of profitability, by which the soundness of any proposed capital investment and the success of performance generally are judged in private business, plays only a subsidiary role in public enterprises. The main criterion used is the degree to which public good is likely to be served by the proposed capital investment and, similarly, the degree to which public good is advanced by the given operations. At the same time subsidiary consideration is also given to the extent to which the invested capital is likely to return to the enterprise, and also the degree to which a particular operation is likely to help the enterprise to be self-supporting. If the likelihood is slim, the investment or the operation may be avoided or at least only grudgingly made or undertaken. Public enterprises are expected to be self-supporting and to operate more efficiently and economically than private enterprises. If they fail in these respects, their performance is deemed to be disappointing and to call for corrective measures. Comparisons with private operations, however, are possible only if there has been some historical experience with them in the field or if the public enterprises operate in competition with some private ones.

PUBLIC ENTERPRISES IN COMMUNIST ECONOMICS

In a communist society, public enterprises generally cover all industry, mining, transport, communication, construction, major trade, and certain segments of agriculture, leaving to cooperative organizations or to private enterprises only the remainder of agriculture, the trade of artisans, the petty trades, and some professions. In all communist societies, and particularly in the more militant ones, public enterprises are expected not only to produce the assigned quotas of goods (and also quotas of profits for the state) but also to help build socialism and the political, military, and industrial power of the state. Accordingly, factory managers are usually members of the Communist Party and each enterprise usually has within it a communist unit which sees to it that the party's objectives are not neglected. The organization of all the public enterprises, however, is not completely uniform in all the communist countries. Particularly great differences exist in their organization in the Soviet Union, Yugoslavia, and China.

U.S.S.R.—In the U.S.S.R. all public enterprises, except such urban services as those of water supply, gas, electricity, street railways, and housing, are controlled by the central government with some help from the constituent republics and regional governments. They are operated under an elaborate hierarchical administrative system and a national long-range economic investment and production plan which is broken down into individual economic plans for the various republics and regions. At the top of the administrative pyramid is the All-Union Council of Ministers assisted by the State Planning Commission (*Gosplan*) and the State Scientific and Technical Committees. Immediately below it are the councils of ministers of the republics, similarly assisted by their two sets of such committees; still further below are the regional economic councils (*sovnarkhom*) likewise assisted by two sets of committees.

Below this administrative, political, and economic hierarchy are the industrial syndicates or combines (*glavki*), below which are the individual enterprises or factories. Each enterprise or factory is managed by a director, who is usually appointed by the regional economic council. He has complete authority to organize the establishment, to hire and fire key personnel, to organize production, and, after consultation with the factory's trade union, to set wage rates. Since the prices of the raw materials which he uses in production as well as the prices and the amounts of capital which he can spend for the improvement of his equipment are largely fixed by superior authority, the only way in which he

can fulfill or overfill his assigned quota is by getting more work out of his workers (by offering them bonuses or by organizing brigades of the more able workers who set the pace of work for all the others) or by economizing on the use of raw materials and in this way bringing down the costs of production and maximizing the profits of the enterprise. He gets his rewards for achieving these purposes in the form of bonuses and promotion to the management of a larger enterprise or to a higher position in the administrative hierarchy. Thus, the director of a Soviet enterprise operates somewhat like a capitalistic entrepreneur. The autonomy of the Soviet enterprises is thus limited largely to the organization of production and to the right to retain profits in excess of the assigned quota and to use them for reinvestment, bonuses, or other purposes.

Yugoslavia.—In Yugoslavia, on the other hand, the bulk of the public enterprises are locally controlled. Only the large monopolies, such as the postal, telegraph, telephone, and broadcasting services, railways, and airlines are nationally controlled. Moreover, the enterprises are vested with a large degree of administrative and financial autonomy. Within the general pattern of the economic plan they fix their own production goals and even prices (except for the prices of some raw materials which are generally set by the national government). They raise a large part of their capital themselves through bank loans and from their own profits, although some part, varying in accordance with the nature of the enterprise, is supplied to them from the government budget. Finally, the workers have a large voice in the management of the enterprises through their own workers' councils elected by secret ballot. The director of the enterprise is selected by a specially created local commission consisting of representatives of the Local People's Committee, the trade union, and the workers' council. The selection is made from among the persons who, in response to the advertisement made in the newspapers, have applied for the job. The nomination by the commission is submitted to the workers' council for approval. The directors of the national monopolies are appointed by the government.

Communist China.—In Communist China, public enterprises are managed in an even more authoritarian manner than in the Soviet Union. Their management is almost military in character, but in the mid-1960s information on their organization and operation was scant.

PUBLIC HEALTH is defined by the World Health Organization as "the science and art of preventing disease, prolonging life, and promoting health and efficiency through organized community efforts." These efforts are directed toward sanitation of the environment, control of communicable infections, education of the individual in personal hygiene, organization of medical and nursing services for the early diagnosis and preventive treatment of disease, and "the development of social machinery to ensure for every individual a standard of living adequate for the maintenance of health." The broad aim of public health, in the view of WHO, is "to enable every citizen to realize his birthright of health and longevity."

The emphasis in public health practice may be either environmental or personal—with the understanding that one approach complements the other. Environmental public health is concerned with the community's physical surroundings; it consists of epidemic disease control and sanitary hygiene. Personal public health influences the group by applying the principles of hygiene through individuals; it consists of preventive medicine, social hygiene, social medicine, and social insurance. These main orders of public health are by no means clear-cut and the terms themselves are ambiguous: thus environmental public health and preventive medicine are often spoken of as covering virtually all public health, while social medicine and social hygiene are, for

many, little distinguishable. The framework below is offered, therefore, only as a convenient guide, not a rigid plan.

ENVIRONMENTAL PUBLIC HEALTH

Epidemic disease control

Quarantine
Epidemiological services
Public Health laboratories
Contact tracing
Vector control
Eradication measures

Sanitary hygiene

Sewage disposal
Water supplies
Food hygiene
Housing
Atmospheric pollution
Radiation hazards
Light, heat, and noise

PERSONAL PUBLIC HEALTH

Preventive medicine

Immunization
Preventive examinations
Health education
Cancer prevention
Nutritional measures
Epidemiological studies of noninfectious diseases
Social surveys
Vital and health statistics

Social hygiene

Infant health
Child and adolescent health
Maternal health
Care of the handicapped
Care of the neglected child
Care of the aged
Mental hygiene
Tuberculosis control
Venereal disease control
Rehabilitation of social casualties, problem families, and unwed mothers
Social welfare

Social medicine

Hygiene in hospital practice
Hygiene of general practice
Rehabilitation of the sick
Health centres

Social insurance

The above groupings are based on a concept of public health that leaves no room for rivalry between preventive and curative medicine: both hospital and general practice are important. The hospital "should organize itself to serve the community in all aspects of health care. . . . It should not limit its functions to the restorative sphere" (WHO, 1957); general practitioners "should embrace the work of communal as well as individual medicine" (Dawson Report, 1920). Both hospitals and general practitioners will find themselves involved with the family, which is of paramount importance to the health of the community.

This article recounts the history of public health and describes special aspects of its development in Europe, the United Kingdom and the Commonwealth, the United States, the U.S.S.R., Turkey, Yugoslavia, and other countries. It then examines various types of public health administrative systems, and outlines international cooperative efforts.

For related information see **HEALTH AND SAFETY LAWS; HEALTH EDUCATION; INDUSTRIAL MEDICINE; MATERNAL AND CHILD HEALTH; MEDICAL CARE, GOVERNMENT; MENTAL HEALTH; PREVENTIVE MEDICINE; and SOCIAL WELFARE.**

HISTORY

From Earliest Times to 1500.—Little is known of public health in early civilizations, but all the evidence suggests that, with few exceptions, it was bad. Disease was probably the chief cause of death; in particular, infant and child mortality throughout many thousands of years was very high—in Rome and in Greece it was customary to wait a week before naming babies, for so few survived. Although it is not always easy to identify diseases from the descriptions in ancient writings, enough is known to state with some certainty that all diseases since differentiated have affected man since earliest times. The ultimate effect of so much disease was to check population growth so that the population of the world advanced only slowly, and at different times and places it is known to have declined.

Yet from earliest times some form of public health has existed, as a conscious effort by authority to apply social, scientific, and medical knowledge to the protection of the health of the community. The teachings of the major religions have aided public health by extolling sobriety, cleanliness, the avoidance of excretal pollution, the maintenance of family life, isolation of infectious persons, and the ritual abstention from foods likely to carry parasites. The latrine and flush closet first appeared in Crete about 1000 B.C. Egypt, Greece, and Rome built model towns

and had excellent sanitary systems. Greece and Rome developed the hypocaust (*q.v.*) and in Rome public baths (*see* BATH) were available to everyone. Rome also began the isolation of infectious disease by building leprosariums. Both Rome and Greece sought to regulate prostitution. India and China practised inoculation against smallpox some time before the Christian era. The Arabic civilization had health departments with sanitary inspectors, and its food hygiene may have been the best achieved at any time before the 20th century. The Arabs also were the first to build hospitals with differentiation between patients. European towns of the Middle Ages were generally well planned, with water supplies and hospitals; leprosy disappeared following the practice of isolation, and primitive measures were developed to limit epidemic spread.

But there were many deficiencies: crowding and squalor in Rome; epidemic and endemic diseases, such as malaria, which prevailed unchecked; neglect of child life; and an almost brutal misuse of human labour in the early industrial undertakings. Lack of scientific knowledge was a handicap, as seen in the failure to differentiate disease, erroneous theories of the epidemic process, and the stubbornly held theory of derangement of "humours" as the cause of illness. Yet enough was known to make a sound basis for public health action: the connection between malaria and marshy terrain, and the worst effects of industrial processes, had been noted by the ancients; maternal and child health was the subject of Galen's first book on hygiene; the specificity of anthrax, measles, scabies, and smallpox was understood by the Arabs during the Middle Ages; and in the early 16th century it was known how to cure and prevent scurvy and how to treat syphilis with mercury.

That none of this knowledge led to effective public health services was due in large part to social attitudes. Those in authority took little interest in the fate of the masses (except for soldiery), and the learned remained aloof from the ill-educated. Galen said of occupational hazards: "The life of many men is involved in the business of their occupation and it is inevitable that they should be harmed by what they do," adding, "and it is impossible to change it." His treatise on hygiene, *De sanitate tuenda* (A.D. 157), was written for the few, and there was no exception to this outlook until the Renaissance. Sickness and occasional hunger were everywhere considered normal attributes of living. Indeed, the population of the world advanced from about 275,000,000 in A.D. 1000 to only about 450,000,000 during the next 500 years.

From 1500 to 1800.—With the Renaissance, ideas about public health began to grow. Sir Thomas More in *Utopia* (1516) described an imaginary country where hygiene protected health, and medicine restored it, and where all that was needed for health was to hand. Other ideas followed, in Daniel Defoe's *Essay upon Projects* (1698), John Bellers' *Essay Towards the Improvement of Physick* (1714), and Lodovico Muratori's *Della pubblica felicità* (1749). Bernardino Ramazzini's *De morbis artificum diatriba* (1700) was the first full-scale treatise on occupational health. John Pringle wrote *Observations on the Diseases of the Army* (1752) and James Lind *An Essay on the Most Effectual Means of Preserving the Health of Seamen in the Royal Navy* (1757). Richard Mead's *A Short Discourse Concerning Pestilential Contagion* (1722) suggested the need for a central council of health with local public health organization.

Social insurance was encouraged. The more enlightened industrialists sought means to protect their workers from the worst of the poisonings. Attempts were made from about 1600 to establish services of one sort or another; e.g., St. Vincent de Paul began home nursing through his Confraternities of Charity in 1617, while *bureaux de santé* were established in many French towns and municipal doctors were appointed in several European states. Many advances began to be made upon Galenic medicine; e.g., Girolamo Fracastoro (1478–1553) suspected that disease was caused by microorganisms, and Anton van Leeuwenhoek (1632–1723) first observed bacteria. The Greco-Roman theory that epidemics are caused by "miasms," or vapours from the earth, declined although Thomas Sydenham (1624–89) reinterpreted it in terms of atmospheric conditions. The increasing differentia-

tion of disease further weakened the humoral theories. Compulsory parish registration and, in London, the bills of mortality—weekly lists of deaths, compiled by house-to-house visiting—particularized the toll of disease. John Graunt in his *Natural and Political Observations . . . Made upon the Bills of Mortality* (1662) provided one of the earliest classifications of disease.

After 1650, improvements in living conditions had a marked effect, particularly in England. Public health gradually improved in all parts of the world, except perhaps in Africa. Infant and child mortality began to decline and population to advance more sharply, so that by 1798 the world population had doubled to reach 920,000,000. But if industrialization raised general living standards, it also depressed those of the workers in the new slums, and it was this side effect more than anything else that determined the spectacular growth of public health activity after 1750.

From 1800 to Modern Times.—Public health from 1800 on was greatly influenced by general scientific progress. Rapid advances in medical science in the 19th century revolutionized ideas about the basis of health. Physiological chemistry gave rise to the science of nutrition; clinical medicine established the specificity of disease. Most important, the centuries-old erroneous theories of epidemic spread were finally routed. Oliver Wendell Holmes (1809–94) in the United States and I. P. Semmelweis (1818–65) in Vienna added puerperal (childbed) fever to the lengthening list of diseases known to be conveyed by human contact. F. G. J. Henle put forward the hypothesis that the infectious process was biological (1840); Sir John Burdon-Sanderson established it in 1866. John Snow published his pamphlet *On the Mode of Communication of Cholera* (1849) and in 1854 gave convincing evidence of its waterborne spread; William Budd did the same for typhoid (1873). The end of the century was notable for Pasteur's identification of pathogenic bacteria and the final disproof of the theory of spontaneous generation. Robert Koch isolated the tubercle bacillus in 1882 and, in rapid succession, the same was done for many common infectious maladies. An important result of the germ theory of disease was the transformation of hospitals. They took on new meaning when the antiseptic principles of Joseph Lister (1827–1912) were applied, and by the end of the century they began to take the chief position in community health services. During the 20th century science continued, by the discovery of vitamins, antibiotics, and much else, to give public health new weapons. The study of society, particularly by means of the social survey, extended the basic concepts of public health, and the medical officer of health became something of a social scientist as well.

International Public Health.—Public health collaboration among countries originated in the fear of epidemic spread and the inconvenience to trade arising out of the practice of quarantine (*q.v.*). From 1851 a series of International Sanitary Congresses was held in the capitals of Europe and the United States, leading eventually to the formation of the Pan American Sanitary Bureau (1902) with headquarters in Washington, D.C.; and L'Office Internationale d'Hygiène Publique (1909) with headquarters in Paris. After World War I the health section of the League of Nations was created (1923) with headquarters at Geneva. It was followed after World War II by the World Health Organization (1948), a specialized agency of the United Nations. WHO, also with headquarters in Geneva, absorbed both the League health office and the Paris office and thus became the sole international health organization, excepting the Pan American Sanitary Bureau, which continued to operate independently but acted also as the WHO regional office for the Americas. Cooperation among the nations has continued in the control of the spread of disease, and has widened into the field of aid in the strengthening of medical services and medical education for the developing countries. *See* WORLD HEALTH ORGANIZATION (WHO).

NATIONAL DEVELOPMENTS

WESTERN EUROPE

The philosophy of public health on the continent was long dominated by the paternalistic concept of absolute rule. The benevolent sovereign devised safeguards for health: he believed that in

doing so he was strengthening the state and increasing its riches. Health protection thus became a function of the state and was supervised by officials referred to as "medical police." The German physician J. P. Frank, in *System einer Vollständigen medizinischen Polizey* (1779), discussed every aspect of public health, with the exception of occupational health. Frank's programs were, for the most part, beyond the capacity of the 18th century, and some, such as health education and the prevention of accidents, were only put into operation much later. Each sovereign state tended to develop public health independently: not even Frank's omnibus of social medicine could impose a blueprint. Sweden pioneered vital statistics (1748); Germany made vaccination compulsory within a few years of Edward Jenner's discovery (1796); Denmark set up a system of gratuitous treatment of venereal disease (1790); the Netherlands and Scandinavia trained the midwife in the early part of the 20th century; France pioneered the infant consultation centre. The European pattern spread to colonial territories and, by association with Germany, to Japan.

In France public health was based upon the *département* under the authority of the *préfet*, a nominated state official, and was dependent on directions from a central government agency. French progressives in the 19th century dwelt upon the need for organized medical care. The marquis de Condorcet in *L'Esquisse d'un tableau historique des progrès de l'esprit humain* (1793) asked for a comprehensive system of insurance to eliminate poverty; J. R. Guérin, editor of the *Parisian Gazette Médicale*, urged (1808) that medicines should be dedicated to society; Philippe Buchez (1899) advocated a national health service with a doctor to each 2,000 persons. A. J. P. Parent Duchâtelet (1790-1836) described prostitution in *De la prostitution dans la ville de Paris* (1836); L. R. Villermé (1782-1863) studied differential mortalities in various districts of Paris and surveyed the health of textile workers. The *préfets* received their first national circular about hospitals in 1840 and most European countries began to build state hospitals at about that time. Denmark and Sweden in 1831 had a hospital system financed by taxes. European nations also early evolved extensive systems of social insurance: Germany (under Bismarck) introduced such legislation in 1883, Austria followed in 1888, Hungary in 1891, Luxembourg in 1907, and Norway in 1909. In contrast, sanitary hygiene tended to be neglected.

UNITED KINGDOM AND THE COMMONWEALTH

Public health in the United Kingdom took a different course. Its administrative system, based on local government with a considerable measure of local autonomy, accorded with a dislike of autocratic rule, while its main emphasis was upon environmental hygiene, largely because of the slum living born of the Industrial Revolution. Edwin Chadwick (1800-90) became secretary to the Royal Commission (1832) on the reform of the Poor Law and was largely responsible for its report. The scheme under which the country was divided into unions of parishes, administered by elected boards of guardians, each board having a medical officer responsible for giving medical care to paupers, was essentially Chadwick's, and he himself became secretary to the Poor Law Commission in London (1834). The new system soon acquired public health functions, including vaccination and the registration of births and deaths. Unfortunately the system was based upon the philosophy of "less eligibility" (i.e., that paupers should be accorded less consideration than labourers) and therefore the principles underlying personal public health were mostly denied in practice.

Chadwick came to appreciate that disease causes poverty, and his emphasis on "the pecuniary cost of noxious agencies" led to advances in environmental public health. His views were underscored by the arrival of cholera, which had left India in 1826 to spread relentlessly across Europe. Persons of initiative and public spirit began to see the need for public sanitary measures. Chadwick, marshaling these new forces, was greatly aided by the publication of extracts from the fourth and fifth annual reports of the Poor Law commissioners, *The Sanitary Conditions of the Labouring Population* (1842). Chadwick's campaign culminated

in passage of the Public Health Act of 1848—a landmark in world public health. The act established locally elected boards of health with powers to appoint a medical officer of health, impose a tax, and remedy sanitary defects by recourse to a sanitary code. The act thus embodied Chadwick's belief that public health should be administered locally, to encourage the people to participate in their own protection; and it implemented his pioneering suggestion that such boards employ medical men as specialist advisers.

Another supporter of health reform was William Farr, whose annual reports as compiler of abstracts to the registrar general made vital statistics the basis of constructive thinking, thus dispensing with what he called "vague conjecture" and powerfully stimulating a wide reading public. Among the many who were influenced by his writings was Florence Nightingale, whose *Notes on Nursing* (1860) called attention to the enormous infant and child mortality and discussed the importance of household hygiene. T. Southwood Smith, who worked with Chadwick on the General Board of Health established by the 1848 act, based his *Philosophy of Health* (1835-37) on the new teachings of science.

By 1872 the country was divided into sanitary areas governed by locally elected bodies, with the duty of appointing medical officers of health. Parliament legislated widely to enable local authorities to enforce public health provisions. This legislation was influenced by John Simon, chief medical officer to the central health department (at the Privy Council) 1848-71, who conducted a nationwide series of socio-medical surveys of housing, diet, industrial processes, infant mortality, worm infestations, and hospitals. The Sanitary Act of 1866 saw the beginnings of industrial hygiene. The Public Health Act of 1875 provided a complete sanitary code which, with consolidation and adjustments, remains in force. A succession of housing acts placed increasing responsibility for housing upon the medical officer of health, ensuring that health became the most important consideration in dealing with slums. The diploma in public health, to be registered by the General Medical Council, was made compulsory for senior posts in the public health service.

The local-government system, and the elaboration of the sanitary code under which it worked, was accompanied by growth of a central organization which supervised the work by inspection and was later to regulate it by grants-in-aid. This trend resulted, in 1919, in the formation of the Ministry of Health, which brought together health functions hitherto scattered among government departments; but it left mental health under the board of control and industrial hygiene under the Home Office (later under the Ministry of Labour). The Ministry of Health reintroduced Simon's scientific approach to health problems and gave to medical officers of health a new feeling of being linked sympathetically with the centre. The reports of Sir George Newman, the first chief medical officer to the Ministry of Health, set a new tone and embodied a new spirit of social and preventive medicine.

During the 20th century the emphasis shifted gradually from environmental toward personal public health. A succession of statutes, of which perhaps the Maternity and Child Welfare Act (1918) was the most important, placed responsibility upon county councils and county boroughs for most of this work, leaving the original sanitary areas—urban and rural districts and boroughs—responsible for environmental sanitation. The boards of guardians were abolished in 1929 and their public health functions transferred to the county councils and county boroughs. National health insurance (1911) gave medical, sickness, maternity, disablement, and sanatorium benefits to 16,000,000 workers. This marked the beginning of a process of socialization upon which, after World War II, the National Health Service Act was to build (see below). Other social legislation between 1944 and 1948 helped to create the framework within which community health problems were reassessed.

The National Health Service Act (1946) provided a comprehensive cover for most of the health services, including hospitals, general practice, and public health; it included all aspects of mental health but not the industrial medical service of environmental public health. Medical care in the hospital and by the general practitioner became, and largely remained, free. The service was

designed to operate, at the periphery, in three distinct compartments: (1) Regional hospital boards, centred upon universities and covering up to 5,000,000 people, took over the running of virtually all institutions for medical care. (2) Executive councils in the areas of counties and county boroughs became responsible for the general-practitioner service. (3) Local health authorities (county councils and county boroughs) were made responsible for many services, including health visiting, home nursing, home helps, domiciliary midwifery, the prevention of illness and the care and aftercare of persons suffering from illness or mental deficiency, and the provision of health centres. Public health under this act was freed from administrative responsibilities for hospitals, but it was made part of a wide scheme of socialization in which the hygiene of both general practice and of hospitals had a new meaning.

The first 20 years of the National Health Service emphasized the community as the subject of public health. Though environmental hygiene and the control of communicable disease were together the prime concerns of the medical officer, he was increasingly concerned with the prevention of disease and with the health and social welfare of the community. Examples of prevention in the 1960s were a notification scheme for congenital abnormalities in the newborn and the routine screening of women for the early detection of cancers of the womb. Similarly, the prevention of mental illness became associated with the growth of community social services for the mentally ill and the mentally handicapped. While the population of hospitals for the mental ill fell, there was an increasing association of general hospitals with psychiatric treatment and with community mental health services. Health education of the community also developed. Thus, dental health education and informing the public of the relation of cigarette smoking to lung cancer and bronchitis were major interests of the Ministry of Health and the Central Council for Health Education. A few local antismoking clinics were set up.

The organization of the health service moved somewhat toward the community as the basic unit. Reports of the Ministry of Health on *Health and Welfare: the Development of Community Care* (1963) and the *Hospital Plan for England and Wales* (1962), each with later revisions, formed the basis for policy; but trends in the 1960s could be seen in the growth of the district hospital concept, in the setting up of health centres such as those at Peckham (London) and Cleckheaton (Yorkshire), in the attachment of health visitors to general practices as in Oxford, and in the growth of continuing medical education for the family doctor.

The Commonwealth.—The influence of the United Kingdom sanitary movement spread throughout the British Empire. Thus colonies, dominions, and many other territories which later became independent began to build public health services with autonomous public health authorities, the medical officer of health, and the sanitary code as their first considerations. In the absence of voluntary and other agencies which could shoulder responsibility, the British pattern of local autonomy had to develop under the authority of the Colonial Office, centred in London. In the virtual absence of corps of physicians and in the face of so much sickness, medical relief had from the beginning to be accepted as a responsibility of government and consequently, as the Bhoire Report (1946) said of India, "Medical relief received much more attention than the development of those preventive services which may collectively be termed 'public health activities'." Although sanitary commissioners were appointed to Indian provinces in the middle of the 19th century, the establishment of an effective local-government system for public health did not begin in India and Ceylon—themselves in advance of other colonial territories—until the 20th century. The development of public health in any real sense began in India only in 1921, after the Government of India Act (1919) had transferred health administration to the provinces. Ceylon established the first of a series of local health units, covering 40,000–80,000 population, in 1926 and soon had virtually complete coverage.

Canada, Australia, New Zealand, and South Africa also developed their public health services much later than did the United Kingdom. New Zealand established services most closely re-

sembling that of the U.K., with free medical care from the general practitioner and in the hospital, the chief distinction being the method of paying the general practitioner by fees for service rather than by per capita taxation. In Canada and Australia public health is a state responsibility and the federal government influences developments by grants-in-aid and consultant advice. Neither has socialized medicine, but Canada pioneered a scheme in Saskatchewan for comprehensive care which goes beyond that of the U.K. in making salaried appointments outside the hospital. South Africa pioneered "family health care" in the health centre at Pholela, and the National Health Service Commission (1944) recommended that the government base a service for the whole country upon such units, each serving about 25,000 people; but cost and other considerations, including the pull of curative medicine toward the hospital, prevented this. (C. F. BN.)

UNITED STATES

Great epidemics of smallpox raged in North America in the 17th and 18th centuries, and repeated yellow fever epidemics characterized the 18th century, especially in New York during the American Revolution. Rigid public health measures were established during these epidemics. Individuals and families, at times whole communities, were quarantined, and ship quarantine measures attempted to prevent importation of disease. But quarantine often failed because of misunderstanding of the complex interrelationships among the disease carriers, modes of transmission, incubation periods, and other epidemiologic factors. Disease contagion was often attributed to bad odours from decaying animal or vegetable matter, and the few public health departments in existence at that time were organized largely for the removal of community debris.

Municipal health boards were created in Baltimore in 1798, in Charleston, S.C., in 1815, and in Philadelphia in 1818. In 1850 an epochal report of the Sanitary Commission of Massachusetts was issued by Lemuel Shattuck and others, and 15 years later a sanitary survey of New York City was completed by Stephen Smith. These reports were early charters for broad public health programs in the U.S. Under their impetus the formation of state health boards was begun. That of Massachusetts was the first (1869), and by 1919 all the states had organized health departments. Local health departments, too, began to increase after 1920. Just before World War I the first full-time county health department was established in Yakima County, Washington.

In 1798 Congress passed an act providing for the medical care of merchant seamen. This was the first federal health program—the forerunner of the present U.S. Public Health Service, first organized in 1870 as a national agency with a central headquarters and a medical officer in charge.

As early as 1799 Congress had authorized federal officers to cooperate with state and local authorities in the enforcement of quarantine laws. Physicians in the marine hospitals also helped communities curb epidemics of cholera and yellow fever. In 1893 Congress gave full responsibility for foreign and interstate quarantine to the Public Health Service, thereby giving uniformity to the laws previously administered by the states.

In 1887 the service established a hygienic laboratory in the marine hospital on Staten Island, N.Y., to apply the new bacteriologic principles to the study of disease in the U.S. This small beginning eventually resulted in the establishment of the National Institutes of Health, research arm of the Public Health Service and the largest supporter of medical research in the country.

The health provisions of the Social Security Act of 1935, which authorized annual grants to states for general health purposes, greatly stimulated the development of health services and strengthened federal-state cooperation. The National Cancer Act of 1937, the Venereal Disease Control Act of 1938, and the Hospital Survey and Construction Act and the Mental Health Act, both of 1946, expanded the health work of the federal government.

The Department of Health, Education, and Welfare was created in 1953, with the Public Health Service as one of its major constituents. Related health agencies, such as the Food and Drug Administration, the Vocational Rehabilitation Administration, and

the Children's Bureau, were also included in the department.

Voluntary health organizations, supported by publicly contributed funds, have increased greatly in number and strength since the voluntary movement was launched in the late 19th century. The National Tuberculosis Association, the American Heart Association, and the National Society for the Prevention of Blindness are examples of voluntary agencies.

Local Health Services.—Local effort continues to play a primary role in the United States. The size and scope of local programs vary, but the following are some of their typical functions: (1) control of communicable and chronic diseases; (2) operation of clinics for mothers and children and for various preventive and diagnostic services; (3) provision of public health nursing services; (4) environmental health services, including inspection, supervision, and sanitary control of water supplies, sewage disposal facilities, milk production and distribution, and food-handling establishments; (5) public health education and information; (6) collection and analysis of vital statistics; (7) operation of community health centres, hospitals, and other facilities; and (8) community health planning, consultation, and coordination.

A modern local health department consists of a corps of health specialists, such as physicians, nurses, dentists, engineers, sanitarians, and health educators, and supporting technical and administrative personnel. In addition, other local agencies often assume responsibility for certain health services or activities: boards of education may deal with school health programs, departments of public works with construction and maintenance of sanitation facilities, and welfare agencies with provision of medical and hospital care.

State Health Services.—Within a single state, health services may be dispersed among numerous separate agencies of state government. Every state, however, has a specific agency, usually termed the department of health, charged with overall health responsibilities. State health work ranges from regulatory or advisory activities to the operation of certain direct services.

State governments usually carry on five types of health functions: (1) public health and preventive services, such as demonstrations of new techniques and programs, and supervision over utilities of public health importance; (2) medical and custodial care, such as the operation of hospitals for tuberculosis and mental illness; (3) expansion and improvement of hospitals, medical facilities, and public health centres; (4) licensure for health reasons of individuals, agencies, and enterprises serving the public; and (5) provision of financial assistance and technical consultation to local units of government for conducting health programs. In addition, most states maintain regulatory authority over most health matters, and promulgate rules and regulations which are applicable throughout the state.

Federal Health Services.—The Public Health Service of the U.S. Department of Health, Education, and Welfare is the principal federal health agency, but several other departments and independent agencies have specific health interests and responsibilities. Federal health agencies are responsible for identifying and helping to meet national health problems, for helping to improve state and local services, for controlling interstate health hazards, and for working with other countries on international health matters. The federal government also has a number of direct health functions, including: (1) protecting the United States from communicable diseases from abroad; (2) providing medical and hospital care for designated beneficiaries, such as members of the armed services, veterans, merchant seamen, and American Indians; (3) protecting the consumer against impure or misbranded foods, drugs, and cosmetics; and (4) licensing and regulating the production of serums, vaccines, and other biological products. In addition, the federal government spearheads a vast medical research and research training effort. In the 1960s the federal government was supporting more than half of the medical research in the United States, in its own laboratories and through grants to universities and other scientific institutions. Federal agencies provide technical services and grants-in-aid to improve health services and resources throughout the country. For example, federal grants matched by nonfederal funds have helped

to build many new hospitals and related facilities since World War II.

Voluntary Health Agencies.—Voluntary effort is a significant part of health work in the United States. By 1960 there were more than 100,000 voluntary agencies in the health field. Most operated at the city or county level, but nearly 300 had statewide activities and about 30 were national in scope. Supported largely through private sources, voluntary agencies make substantial contributions to public and professional education, research, and programs of medical and hospital care in their respective fields of interest. An agency's interest may centre on a specific disease, such as tuberculosis, cancer, or arthritis; on safeguarding specific bodily functions, such as vision or hearing; or on promoting the health of a special group, such as mothers and children, the aged, or the handicapped. Other nongovernmental groups which contribute to total health services or resources in the U.S. include hospitals, foundations, private laboratories, professional organizations, schools and universities, industrial and labour groups, and civic organizations.

Progress in Public Health.—There is a great variety in the type, content, scope, and quality of performance of health services in the United States. Moreover, these services are provided by a multiplicity of independent agencies; e.g., the three levels of government—federal, state, and local (city or county)—represent distinct and separate entities. In effect, however, they constitute a working partnership for the protection and promotion of human health. Moreover, they work closely with voluntary agencies, professional groups, schools and foundations, management and labour, and families and communities to control disease and improve well-being. The result has been a consistently upward trend in both individual and community health. In 1900 there were 17.2 deaths from all causes per 1,000 population; in 1963 the rate was 9.6. The infant death rate for 1965 was 25.4 per 1,000 live births, compared with a rate of 100 in 1915. In 1935, for each 10,000 live births, 58 mothers died; in 1963 there were 3.7 maternal deaths per 10,000 live births. Since the turn of the century there has been a gain of more than 20 years in life expectancy: from about 47 years to almost 70 years.

Most dramatic has been the continuing success against the infectious diseases which were once the chief causes of death among children. The principal communicable diseases of childhood—diphtheria, whooping cough, measles, and scarlet fever—had a combined death rate of 243 per 100,000 children under 15 years of age in 1900, but they accounted for only about 1 death per 100,000 in this age group in the 1960s. Other infectious diseases, such as smallpox, typhoid fever, pneumonia, gastrointestinal infections, and trachoma, have also been greatly reduced. Tuberculosis mortality fell from a rate of 194 per 100,000 in 1900 to 4.2 in 1965—a drop of nearly 98%. From 1945 to 1951 the average annual decline for this disease rose to 10%, and after 1951 there was an average 21% drop in the death rate each year. The death rate for syphilis fell from 16 deaths per 100,000 in 1938 to 1.5 in 1965.

The chronic diseases constituted the major health problem in the U.S. throughout the 1960s. Cancer and heart diseases together caused more than 70% of all deaths in 1963. These diseases, plus diabetes, arthritis, neurological defects, and mental illness, as well as accidents, accounted for much disability, long-term illness, and hospital care in the U.S. Public health agencies in the U.S. are turning increasingly to the control of these diseases; to the health problems of an aging population; and to the environmental problems associated with a complex industrial and social environment: water and air pollution, unhygienic housing, preventable accidents, the hazards involved in the widespread use of chemicals and ionizing radiation, and emotional stress. (L. L. TE.)

OTHER COUNTRIES

After World War I the U.S.S.R., Turkey, and Yugoslavia sought to achieve in a few years what Western Europe and the U.S. had accomplished in two centuries. The U.S.S.R. and Yugoslavia had been influenced by European developments in public health—the former had established a form of local government, the *zemstvo*,

employing salaried doctors responsible for both curative and preventive medicine in their districts, and the latter had taken part in Austrian public health developments—but all three were typical underdeveloped countries with high infant and child mortality, low expectation of life, widespread infectious and nutritional diseases, and an almost complete lack of sanitary science.

The principles upon which public health in these countries is based are as follows: complete integration of curative and preventive medicine, medicine as a social service, the predominance of preventive medicine, health centres as the basis of operation, and community participation. These are mainly remarkable for the fact that they were put into operation in the early 1920s, for in themselves they go little beyond the statements made in various white papers which preceded the National Health Service in Britain, or the many national and international reports.

In the U.S.S.R. administration is centralized, with little local autonomy. Standards laid down by the union ministry are administered by the republic through special departments; day-to-day work is conducted by regional and district committees. For many special services, *e.g.*, health education, there are central institutes for research and administrative direction. The chief element in the Soviet system is the polyclinic, a health centre which, in effect, combines the primary and secondary health centres recommended in the Dawson Report. It employs three types of salaried physicians, on a whole-time basis: (1) general practitioners who cover a defined sector; (2) specialists who work in the centre; and (3) public health experts. The centre does most of the work performed in Western Europe and the U.S. in hospital out-patient departments, including preventive examinations by a team of specialists—the method known as dispensarization—and factory health, school health, and maternal and child health work. The training of doctors is designed to use medicine as a social service, and emphasizes the principles of public health; students can specialize in general medicine, sanitary and hygienic work, or pediatrics. The U.S.S.R. system also makes use of soviets; *i.e.*, village or street committees. The 70,000 soviets are responsible for sanitary matters, for seeing that care is given where needed, for work in connection with problem families and marital disharmony, for following up the schoolchildren, for inquiries in relation to surveys, and much else. The social effects of this committee system upon public health work are considerable.

Yugoslavian public health has many of the features seen in the U.S.S.R.: there are health centres and doctors practise largely on salary. But there are many differences, the most striking being an Institute of Hygiene, combining administration and research, in each of the nine republics. After 1948 there was a decentralization of health activities, permitting a considerable measure of local autonomy; town councils, industries, and hospitals, or groups of hospitals, were given powers to manage their own affairs within their respective budgets—hospitals budgeting on the basis of payments for beds from social security funds, industries and town councils on an allocation of industrial profits.

Turkey, with a different political philosophy but an equivalent degree of centralization of powers, took another course. As did the U.S.S.R. and Yugoslavia, it developed the health centre as a focus of preventive and curative work—but in the form of a rural hospital. The Ministry of Health and Social Assistance controls the organization through directors of health in the provinces, the governor of the province being head of the provincial health board, composed of officials. Corresponding district boards exist and a socialized health scheme was being introduced in stages. At the same time new emphasis was being placed on medical and public health education and on the training of health administrators.

After World War II public health advanced notably in Indonesia, Burma, Thailand, the South American states, China, India, and Pakistan. The period was remarkable for the influence of the World Health Organization and of other agencies of the United Nations. The health problems facing these countries were even greater than were those of the U.S.S.R., Turkey, and Yugoslavia in the 1920s: communicable and nutritional diseases abounded; intestinal infections and worms of many kinds were almost universal; special diseases, such as yaws, filariasis, and

leprosy, prevailed over wide areas; lack of sanitation caused untold illness; childbirth remained in the hands of village midwives; so that in Indonesia a woman was said to die in childbirth every quarter of an hour and a baby every minute; Indonesia had one doctor to 57,000 people. Moreover, the social framework upon which health services depend had hardly begun to develop in most cases: there was an absence of scientific background, while deeply rooted customs and beliefs made progress difficult.

Success in these circumstances was inevitably limited. Most of these countries had centralized schemes for the eradication of special diseases, often undertaken with the help of international bodies or financed by interested nations. In Brazil there were national services for malaria, leprosy, yellow fever, mental diseases, cancer, plague, and tuberculosis and national agencies for port health, biostatistics, drug control, and health education. Nevertheless large parts of Brazil and of other countries were without local services. Thus in Bolivia, where systematic vaccination began in 1953, the Pan American Sanitary Bureau reported in 1956 that it had been impossible to eradicate smallpox because of the lack of an adequate organization to carry out vaccination on a national scale. Special schemes helped to fill in the gaps: in eight South American countries the reporting of communicable disease was done by "reporting areas."

Perhaps the most important expedient in these countries was the development of the model health unit, in which personnel could be trained and schemes suitable for the country tried out. Such model units, as at Bandung, Java, and Sinpur, Bengal, were the obvious first step at the local level. The training of new types of public health personnel, such as the home visitors in Indonesia, health assistants in Burma, and village workers in India, was important. Most of the countries new to public health also developed health centres. Thus Burma set out in 1941 to establish 800, using health assistants with 21 months' training, and by 1957 there were 300 centres in operation. India implemented the Shore Report in this and other respects, and in the state of West Bengal there were more than 100 health centres by the 1960s.

Much was accomplished in little time, but it was clear that public health needed to develop a permanent framework, a sound organization at the local level, which could not only begin the services but also maintain them. Many countries, sometimes with the assistance of WHO, have developed national plans for promotion of indigenous medical education and for the increase of community medical services. (C. F. Bn.)

ADMINISTRATIVE SYSTEMS

The Central Organization.—The forms and functions of central government administration in health matters vary from country to country. There are two main types of central health organization. One is the grouping of major health functions in a separate department; *e.g.*, the Ministry of Health in the United Kingdom and the Commonwealth Department of Health in Australia. The other is the organization of health functions in a department responsible also for closely related functions; *e.g.*, the Department of National Health and Welfare in Canada and the Ministry of Social Affairs and Public Health in the Netherlands. In some countries health functions are organized in the same department with the social insurance program; *e.g.*, the Ministry of Social Security and Health in Ecuador and the Department of Health, Education, and Welfare in the United States.

The official responsible for the administration of national health affairs is, in many countries, a member of the cabinet. His political leadership is of great value in the development of a national program; his cabinet position ensures proper consideration of health problems at the highest level of public policy. The chief executive officer of health is almost universally a physician appointed according to the laws of his country. A minister or a chief executive may change with the party in power, but this lack of continuity in administration is generally overcome by the appointment of a permanent staff of professional and administrative personnel to head and operate the main departments. The United Kingdom is a partial exception to the rule that the executive officer is a physician: full executive power is vested in a permanent

secretary; the chief medical officer advises the permanent secretary and himself has a right of approach direct to the minister. In the United States the surgeon general of the Public Health Service is a physician selected from a corps of commissioned medical officers and appointed by the president; this device, provided by law, ensures that the chief executive of the Public Health Service will always be a physician drawn from a group employed permanently in government service. The surgeon general is responsible directly to the secretary of health, education, and welfare.

Advisory councils are employed almost universally in the administration of national health programs. These bodies vary widely in composition, functions, and methods of operation but they invariably bring to bear on national health problems the thought of leading scientists, health personnel, and, in some instances, community leaders. As a rule the functions of councils are limited to giving advice but in some instances the decisions of a council are binding. Most central health departments have one general council whose function is to advise on overall planning, organization, and administration; e.g., the Central Health Service Council in the United Kingdom and the Scientific Medical Council in Hungary. There may be many additional councils or committees dealing with particular programs, as in the U.S. Public Health Service, which has 12 advisory bodies authorized by the Congress and more than 100 *ad hoc* committees.

Few, if any, central departments of health are all-embracing; departments of industry, education, housing, labour, insurance, welfare, and agriculture may operate medical services of one kind or another. No country has concentrated the medical services for its military forces in the central health agency. Even countries with fully socialized health services place important health functions under ministries other than the ministry of health. In Denmark and the U.K. industrial and school medical services are under separate ministries; in the U.S.S.R. the ministries of transportation, river fleet, food industries, social security, and internal affairs have responsibility for specialized health functions. Since unity of control at the centre is virtually impracticable in the ever-broadening field of health, coordination is most important. Advisory councils may play an important role in coordinating activities if their membership includes representatives of other government departments having common interests in health. Planning commissions, interdepartmental councils or committees, and other coordinative devices have been adopted successfully.

Central administration is further complicated in a federal system. In the U.S. there are 50 states, no two of which have the same distribution of health functions in the structure of state government. There is also considerable differentiation in the type of state health organization. In about half of the states a board of health is the governing body, as illustrated in Minnesota, where a body of "nine members, learned in sanitary science . . . shall be appointed by the governor to serve without pay for overlapping three-year terms." The boards vary in number of members and composition, some being composed entirely of medical practitioners. A governing board of health usually has broad authority to adopt regulations which have the force of law, to approve the budget, and to appoint its chief executive officer, with or without the approval of the governor. Other state departments of health have advisory boards or councils, but they vest full administrative authority in a medical officer appointed by and responsible exclusively to the governor. The powers and functions of state health departments, however, are defined by the state legislatures which also appropriate the funds for state services and have exclusive authority over local governments.

To improve coordination between national and state health administrations, the surgeon general of the Public Health Service and the chief of the Children's Bureau (Department of Health, Education, and Welfare) confer annually with the 54 health officers of the states and dependencies of the U.S. The surgeon general also confers with state hospital and mental health authorities. Nine regional offices of the department serve groups of states with consultation on their health and welfare programs. Other federations have adopted effective coordinative devices; e.g., the Central Coun-

cil of Health of India has the union health minister as chairman and the state health ministers as members. It was established "to consider and recommend broad lines of policy with regard to health in all its aspects, including remedial and preventive care, environmental hygiene, nutrition and health education, and the promotion of facilities for training and research." The Dominion Council of Health of Canada meets twice a year under the chairmanship of the deputy minister of national health and welfare. Its membership includes the administrative head of each provincial health department. The council "acts as an agency for promoting joint planning between the federal government and the provinces, and between individual provinces."

Federal grants-in-aid to states or provinces also help to unify health programs in most federations.

The Local Health Unit.—This is the name given to an organization which provides basic community health services under the direction of a medical officer; it is usually governed by a local authority. Its functions include maternal and child health, communicable disease control, environmental sanitation, maintenance of records for statistical purposes, health education of the public, public health nursing, and medical care. Wherever possible school medical services are also included, since these services enable the findings in school to be related more easily to the home, and ensure that the community nurses, or health visitors, are also the school nurses and that the medical officer of health acts as the administrative medical officer.

The local health unit is a suitable administrative device for the development of a much wider range of community health services, particularly for the care of the aged, the physically handicapped, and the chronically ill. Mental health services may be provided through the local unit. Occupational health may be included, as in Yugoslavia, but in many countries, including the U.K., this service has been developed independently. Social welfare service also may be provided by a separate agency; but there are great advantages in amalgamating health and welfare service, since it is not possible to separate the family's health and social problems. In rather more than a third of the local authorities in England and Wales, welfare and public health have been amalgamated; whereas in the U.S. local health and welfare services are almost universally administered by different departments.

In general terms, the population served by a local health unit should not exceed 150,000; but this depends upon many factors, including the size of the territorial area and the location of trade centres, as well as the political jurisdictions involved. In the U.S., for example, a county of 10,000 sq.mi. with a population of 6,000 and a municipality of 300 sq.mi. with a population of 2,000,000 present entirely different administrative problems. The term "local health unit" is often applied only to an organization serving a mixed urban and rural population of 10,000–50,000. Health services in cities and large towns are usually organized in departments comparable with those of state or provincial departments of health. It is possible to overcome the problem of population size by organizing the city health department in districts, each with its medical officer of health responsible to the city health officer. This was done in Toronto, New York City, and Baltimore, as well as in the larger counties (1,000,000–5,000,000) of the United Kingdom.

In the United States increased urbanization since World War II created very large metropolitan areas cutting across county lines and in some instances involving two or even three state jurisdictions. The solution of health problems in these suburban communities and central cities became a major concern of American public health.

The governing body of a local health department may be an *ad hoc* authority which undertakes nothing but health functions, similar to the local boards of health created in England and Wales under Chadwick's act of 1848. In European and most U.S. communities it is generally the town or county council which governs health services together with other community functions, the great advantage of this arrangement being that the medical officer of health can exert a wider influence. Some see in this a good reason for continuing local health administration through town and county

councils; others have advocated a system of regional health administration, following the lines of hospital regionalization.

Medical Care in Public Health Administration.—Medical and hospital care is provided as a public service in some degree by most countries. Public medical service may be limited to hospitalization of patients with certain ailments; e.g., mental disease, tuberculosis, chronic illness, and acute infections. Comprehensive health services may be provided for certain population groups, as in Canada and the United States where the federal governments provide such care for Indians and Eskimos. Many countries have compulsory sickness insurance; some combine the socialization of hospitals with sickness insurance covering general medical care, as in Denmark. Full-scale socialization of health services exists in a few countries, including the U.K., the U.S.S.R., and New Zealand.

Some degree of general medical and hospital care is provided as a public service for the needy even in countries that offer a limited range of health services for the civilian population. In federal systems the state or provincial governments are responsible for the development and administration of medical and hospital programs, as well as for public health services, with varying degrees of control and subsidy by the central government. Federal grants-in-aid, consultation, and technical services may be provided for medical care, health programs, and the construction of hospitals and other health facilities. General medical care is almost universally administered by departments of health; however, most states of the U.S. place this responsibility in their welfare agencies.

In countries where voluntary and nonprofit organizations support a considerable share of the health services and operate most of the general hospitals, as in the Netherlands and the U.S., there is bound to be pluralism in health administration. This makes coordination difficult; but strong voluntary effort has the advantages of involving citizens directly in the development of their health services and of infusing the administration with a spirit of experimentation often lacking in governmental services.

All countries experience difficulty in some degree in overcoming the barriers between health personnel with different interests and experience: hospital staffs and practicing physicians are traditionally oriented toward therapy in the acute stages of disease or injury, public health staffs toward preventive measures applied to individuals and community environments. Comprehensive health care aims to apply preventive, curative, and restorative services using all the instrumentalities of modern medicine and environmental science. The objectives are to prevent disease if possible, to give sick people the best available care in all stages of their illness, to rehabilitate the disabled, and to improve the health of the whole community. None of the existing administrative systems was fully achieving those health goals in the second half of the 20th century.

The Place of the Hospital.—Hospitals tended to grow up haphazardly, with little relation to one another and much duplication. General hospitals were located mainly in cities and large towns; outlying districts in consequence were poorly served. Special hospitals for mental disease, chronic illnesses, and infectious diseases often were constructed in isolated places and developed outside the main stream of scientific medicine. Advances in public understanding, medical knowledge, and therapy have been changing this situation; more general hospitals are providing psychiatric and tuberculosis services for diagnosis and intensive therapy, supplemented by community services for home care, follow-up, and rehabilitation.

The growth of the modern general hospital tended to shift the emphasis toward institutional care and away from care of patients in their homes and clinic facilities. In many countries, changes in the patterns of disease and of family life also encouraged hospitalization as the preferred method of receiving and delivering medical services. Hospitals became a first requisite in the development of community health services. In parts of the world where community health services are being provided virtually for the first time, the building of hospitals has priority. In highly developed countries the ratio of hospital beds to population rises as high as 7–10 per 1,000, of which approximately half are in mental

hospitals. In the 1960s many of these countries were attempting to provide adequate community general hospitals in outlying areas, while increased urbanization and deterioration of the older city hospitals were sharpening the demand for expanded hospital facilities in metropolitan areas.

Regional plans for hospital care are based upon a medical centre, usually a university medical school or a teaching hospital, which has facilities and specialists to deal with all types of illness, especially the more complex, and conducts scientific investigations. Intermediate hospitals in the larger communities provide basic medical and surgical services for their own localities and for patients referred from outlying areas of the region. At the periphery there are community and cottage or rural hospitals, the latter often little more than diagnostic or health centres equipped with a few beds for obstetric cases and emergencies. A two-way flow of patients and specialists takes place from periphery to centre and there is integration with public health under a broad overall plan. Regionalization, nowhere fully achieved, is most advanced in Europe and least so in North America, where voluntary hospitals provide most of the short-term general services and retain autonomy in their administration. In Canada and the U.S., however, hospital construction with federal grants is based on regional planning and in some parts of both countries services emanate from certain medical centres.

The Place of the Family Physician and the Health Centre.—There are many reasons to favour the family as the focal point of community health services. The family is the first defense in maintaining health, preventing disease, and caring for the sick; its characteristics largely determine the patterns of health and disease in the community. Logically, therefore, the family should have a physician to care for it as an entity. In the mid-20th century the belief in the family practitioner as the basis of a community health service led to the idea of the health centre. This term is usually limited to the type of institution which brings together into one building: (1) general medical practitioners; (2) nurses, midwives, social workers, and other paramedical workers who serve families in the same localities as the physicians; (3) preventive clinics; (4) diagnostic facilities; and (5) facilities for health education. The health centre was advocated in the Dawson Report (England, 1920), the Bhore Report (India, 1946), the report of the National Health Service Commission (South Africa, 1944), and other national reports, as well as by a committee of the World Health Organization (1952–54).

The health centre is distinct from a hospital although, as in rural health centres in Turkey, it may have a few beds for general nursing and midwifery. There is no reason, however, to exclude a community general hospital as the administrative locus of a health centre, provided that facilities and personnel for the objectives of both institutions are made available. The growth of medical science and the increasing complexity of its techniques in the second half of the 20th century have indicated that administrative integration rather than separation of hospital, medical, and public health services may prove to be the most effective system of the future.

PUBLIC OPINION. There is little agreement among political scientists, sociologists, and social psychologists on the exact meaning of this term. It has been loosely used to denote the

firmly settled convictions of a group; to denote the process of developing opinions, as distinguished from the product; or to denote statements that are the result of a process of logical reasoning as contrasted with those arrived at by illogical means.

Nineteenth-century commentators stressed the rationality of the opinion process; those of the 20th century do not. In 1828, W. A. Mackinnon declared, "Public opinion may be said to be that sentiment on any given subject which is entertained by the best informed, most intelligent, and most moral persons in the community, which is gradually spread and adopted by nearly all persons of any education or proper feeling in a civilized state." Later, A. L. Lowell wrote that, "An opinion may be defined as the acceptance of one among two or more inconsistent views which are capable of being accepted by the rational mind as true" (A. L. Lowell, *Public Opinion in War and Peace*, Harvard University Press, Cambridge, Mass., 1923). After 1900 the developing science of social psychology increasingly emphasized nonrational factors involved in the opinion process; and the manipulative techniques of the practitioners of publicity, advertising, and propaganda further eroded faith in rationality. Political democracy, however, holds to the principle that the opinions of some men are based on reason and that it is possible to bring popular judgments to positions that are rationally defensible.

According to one definition, relatively stable beliefs should not be considered a part of the opinion process. A state of agreement following an opinion controversy is referred to as a consensus. There is consensus of the type that Montesquieu designated the *esprit général*, that Rousseau spoke of as the *volonté générale*, and that the English theorists called "public will." Wilhelm Bauer wrote of organic opinion as the relatively fixed views as distinguished from transient opinions. But one may consider that public opinion deals with those topics which are controversial and discussible and not with those on which opinions are firmly fixed.

History.—Plato denied the value of any general public opinion. In the main, Roman authors had little respect for mass opinion. It was not until the late 18th century that Alcuin's statement to Charlemagne, *Vox populi, vox Dei* ("The voice of the people is the voice of God"), was quoted approvingly by any substantial group of political theorists. In France, Rousseau and later Necker gave approbation to public opinion and frequently used the term *opinion publique*. In England, in the writings of Jeremy Bentham there was insistence on the significance of public opinion as a basic social control on the excesses of misrule and as a basis for the democratic state.

In the ancient civilizations, public opinion played some part, but the publics were limited in number and size, the mechanisms for expression of opinion were rudimentary and communication was limited. Among the Greeks, public opinion developed to an extent unequalled until modern times; among the adult free citizens who took part in public life argumentative conversation developed and the art of dialectics was codified. The wide-ranging conquests of Rome provided information about many peoples with their values, religions, economic and political systems. Combined with Rome's urban culture, they gave increased scope for the opinion process. There was much to discuss, the culture was dynamic, the opinion process was stimulated and the Romans came to speak of the *vox populi*.

Through the Middle Ages, when people lived in scattered, small groups and agrarian communities and when cultures were blanketed under a common religious ideology there could be little dynamic popular opinion. Rather, there was popular acceptance of the forms of government and submission to the religious hierarchy, not the support of popular opinion.

The opinion process was revived when the Reformation questioned clerical authority and emphasized the individual. Arts, letters, and science began to cast off the bonds of authoritarian revelation. Public opinion began to develop as larger groups became concerned with religious issues, political systems, relative values, and with ideologies in general and the new means of communication, printing, coupled with a slowly growing literacy, disseminated the ideas. The Enlightenment of the 17th and 18th centuries marked a further turning from the authority of divine

revelation to the authority of reason and human understanding. When "natural reason" was posited, then individual opinions became important, and the theorists turned to an examination of the opinion process.

Modern Public Opinion.—It is evident that the opinions of large publics became increasingly important during the 20th century. Economic groups depended upon influencing large publics by publicity and advertising. Through publicity agents, notable personages attempted to create their own legends in the minds of the general public. Commercial advertising became a partial science and the arts of publicity and propaganda were cultivated. The struggle for power and for the control of opinion was conducted by interest groups implemented with the newer means of communication. Authoritarian states meticulously organized propaganda bureaus, while democracies were reluctantly drawn into political and cultural publicity. The problem became one of values. Was the objective the unity of mass opinion for the furtherance of the purposes of the state and of private interest groups? Or was the preeminent value the integrity of the individual's psychological experience? For both objectives the modern facilities of press, radio, and television provided the channels. Opinions were solicited and expressed upon the widest variety of controversial topics ever presented simultaneously to large publics on matters of morals, religion, education, the details of government, the choice of consumers' goods, and the administration of justice. Advertisers of consumers' goods, politicians, and representatives of interest groups clamored for attention.

Measurement and Polling.—In the democracies, the many interest groups attempting to mold opinion desired an effective check on their results. Though there had long been those who sought to discover public opinion by means of interviews and straw votes, it was not until the emergence of the public opinion polls in the mid-1930s that systematic representative sampling of large publics occurred. Two fundamental problems were involved in the measurement of public opinion:

1. Developing tests sufficiently comprehensive to include at least the more typical opinion positions of most of the individuals of a public. Such tests were conducted by interviews, questionnaires, observations of behaviour, yes-or-no type of questions, multiple-choice tests, rating and ranking tests, and attitude scales, such as those of L. L. Thurstone and Louis Guttman. Motivation research testing for advertising and marketing purposes utilized word tests, picture and cartoon tests, thematic apperception pictures, and Rorschach tests (see *PSYCHOLOGICAL TESTS AND MEASUREMENTS*).

2. Developing adequate methods to report on the opinions of large publics, numbering millions of individuals, by means of the smallest possible representative sample. The representative sampling procedure in public opinion surveying is called polling, and early polls on candidates and issues were referred to as straw polls. The pioneer commercial pollsters, or pollers, in the United States were Elmo Roper and Paul T. Cherington, who established the *Fortune* survey, George H. Gallup, originator of the American Institute of Public Opinion, and Archibald Crossley who originated the Crossley Poll. They used polling in an attempt to predict the results of the national elections of 1936. The pioneer pollers had had previous experience as market research men. In addition to the commercial pollers, various university-sponsored polling organizations, some polls maintained by newspapers, and a few by governmental agencies, both state and national, were established. Similar polling organizations were later set up in more than a score of other countries.

Sampling.—In public opinion measurement, the objective is the selection and polling of a representative sample of the group which constitutes the public under consideration. The public selected for sampling might be the adult inhabitants of a single town, the lawyers of the state of Illinois, the population of the whole United States, or any other of the many thousands of publics. Samples used for the entire population of the United States range from small samples of possibly 2,500 to large samples of 10,000. After the persons to be interviewed are selected (the sample) from the public under consideration (the "universe"), they are ques-

tioned by interviewers from the field staff of the polling organization.

Before the use of specially selected samples (made representative by stratified and area-probability sampling), polls were conducted by ballots printed in newspapers or magazines, which could be clipped and returned, by ballots left in stores, by interviews among crowds and on the streets, and by mailed ballots sent to address lists variously obtained. In 1936 the *Literary Digest* mailed over 10,000,000 ballots, received back 2,376,523, and incorrectly predicted the 1936 national election by understating the vote for Pres. Franklin D. Roosevelt by 19.3%. Large numbers alone do not assure representativeness of the sample.

More scientific polling stressed the selection of representative samples of publics. Prior to 1952, most pollers used chiefly the quota sampling methods in which the sample was a small-scale model of the larger universe. For example, a sample of 10,000 individuals to represent the entire voting population of the United States would be selected. The sample would be based on appropriate quotas in proportion to the frequencies in the general population of individuals by age, sex, economic position, community size, past party affiliation, and sometimes a few other criteria. These were the strata. The interviewer would then seek for individuals who would fit the requirements of his assigned interviews. Such stratified sampling permits tailoring the sample to those in the population who are expected to be more significantly involved in the particular opinion topic than the generality. This is an advantage. Moreover, stratified sampling can be carried on in smaller geographic areas than area sampling and is, therefore, much cheaper. Also, it is not necessary to call back again and again to interview the person at a particular address as is true of area sampling. But an objection to the method was that it depended upon the often inexperienced judgment of the interviewer in selecting the particular individual to be interviewed and also that the poller could not always be certain as to the frequency and significance of the various factors used as the strata.

Probability, or random, sampling, on the other hand, a more recent and less tested procedure, aimed to choose the sample in such a way that theoretically every individual in the universe would have an equal chance to be included in the sample. Such sampling originated from making selections by random methods from finite, discrete objects. Applied to populations, it would mean selecting every n th person from the total population as recorded in lists of names or other complete censuses. In polling practice the selection is generally made in terms of location of the individuals in space. From the 3,000 counties of the United States a sample would be drawn; from the counties selected, a sample of rural-urban population drawn; and within these areas, households and individuals would be systematically selected. Area sampling is not based on assignment of quotas, thus eliminating interviewer judgment and possible bias. In area sampling, certain areas (block, section, ward divisions of city or town, section, township, or other area of county, county or other division of state) are assigned to the interviewer. Within these areas he interviews every n th individual or member of a family located at an assigned position (the second house from the northeast corner of a block, etc.). The area units are selected randomly in various ways. Due to travel expenses, time consumption for the interviewer in proceeding from one interview to another remote interview and other costs, area sampling is very much more expensive than quota sampling.

The 1944 area sampling procedures of the U.S. Census Bureau provided the first serious use of area sampling. In 1952 area sampling was first seriously used by commercial pollers to supplement quota sampling in the election of that year. Subsequently it was increasingly used by pollers.

Criticism of Opinion Polling Methods.—Possibilities of error exist at every stage of polling. Sample selection, question selection and formulation, the interview with its possible misunderstandings, the coding and interpretation of answers require experienced, skillful, and honest pollers. Prophecy as to future opinion trends, which is involved in election predictions, is an art of a still higher order. In the 1948 presidential election in the

U.S. the leading public opinion polls showed Dewey ahead of Truman, but Truman was the victor on election day. In the 1960 election the major polls showed a very close race with Kennedy the probable winner, which was how it turned out. In 1964 the polls were unanimous in predicting Johnson's landslide victory over Goldwater, giving rise to some criticism that the polls created a "bandwagon effect."

Some political theorists, congressional investigating committees, and social scientists object to widespread use of public opinion polls for such reasons as their alleged employment to force premature executive and legislative decisions, the possibly adverse implications for political parties of election predictions, supposed methodological errors, and an inferred desire for vague, unfathomable public mind-life in preference to attempted exactitudes. The partial failures of the pollers on some election predictions have elated some political theorists who really disapproved of the polls on grounds other than their accuracy (for example, the numerous polls might encourage popular, rather than representative, democracy); have aroused partisan politicians who were fearful of the polls' influence on voters; have given some social scientists an opportunity to criticize polling methods; and have delighted many aesthetes, comedians, and competing prophets. Others vaguely resent public opinion polls as another threat to privacy in an age in which privacy is already grievously assaulted. The polls may, however, be defended as reasonably accurate reporting on both the significant, matured opinions and the ephemeral sentiments of large publics.

PUBLIC RELATIONS, loosely, the activities connected with interpreting and improving the relationships of an organization or an individual with the public.

History.—The term public relations did not come into general use until after World War I, but many of its basic activities are as old as history. In the 5th century B.C., the Greek poet Simonides put his muse at the service of publicity, selling songs of praise. This practice seems to have been generally considered in bad taste, but even the fastidious Pindar accepted money from those he glorified in his odes. Plato in the *Republic* attacked poets as special pleaders and advocated the suppression of all except those hired by the state to serve its welfare. In the Middle Ages, wandering minstrels were made welcome at great castles largely because of the influence on public opinion they were able to exert on behalf of their patrons. The medieval guilds performed a public relations function for their members by maintaining the standards and dignity of their crafts, though, in contrast to modern trade associations, the guilds emphasized the "mysteries" of their vocations.

In the early 16th century, on behalf of the Augsburg banking house of Fugger, Konrad Peutinger, humanist scholar and adviser to the emperor Charles V, wrote a series of essays on the moral and legal aspects of trade, pointing out that merchants were frequently forced to sell their goods at a loss, and maintaining that

accordingly every trader should be free to get as high a price for his wares as he could. He argued also against restrictions on monopolies and cartels. Largely because of Peutingen's work, the Augsburg council voted to do away with restraints on business.

In England, up to the middle of the 18th century, when it became possible for writers to look to the public for their livelihood, it was not unusual for authors who lacked private patrons to write for political groups. Swift put his talent at the disposal of the Tories, Prior and Addison at that of the Whigs. From 1731 to 1741, Walpole used nearly £50,000 of secret service funds to pay writers and printers. In France, Racine and Molière were among the distinguished writers who supplemented their incomes by writing eulogies of royalty. Napoleon Bonaparte made adroit use of opinion-molding techniques throughout his career.

19th and 20th Centuries.—In the early 19th century, U.S. newspapers frequently granted the hospitality of their news columns to publicity stories in return for paid advertisements. Other papers, inadequately staffed, accepted contributions without close scrutiny of the motives of the writers. Shortly after the Civil War, land promoters, railroads, politicians, and financial groups were making systematic use of such opportunities. In 1869 James McHenry, press representative of the Fisk-Gould financial group, obtained wide publication of material in the group's interest. Soon after this, a number of business and political organizations installed publicity departments, under the name of "literary bureaus."

In the last decade of the 19th century and the first of the 20th, publicity men were multiplying in New York City, most of them former newspaper reporters. Knowing the ingredients of a lively newspaper story, some of them—particularly theatrical press agents—drew freely on their imaginations. In 1909 the American Newspaper Publishers Association, alarmed at the spread of press-agentry, appointed a Committee on Free-Publicity. One bulletin issued by it listed 757 "space grabbers."

Nonetheless, most newspapers continued to use a substantial amount of material from publicity sources. A parallel situation occurred later in Britain. *Report on the British Press*, published by Political and Economic Planning in 1938, stated: "Some newspapers are very much opposed to accepting material from press agencies, and not long ago the Home and Southern Counties Newspaper Federation, representing nearly 300 newspapers, made a concerted attempt to eliminate it. Nevertheless, many of these newspapers continued to print such material, the news-value in them proving too strong a bait."

Till the early years of the 20th century, leaders of business and finance had been opposed to any publicity except commercial puffs and had strongly rebuffed newspapermen. The banker George F. Baker told a reporter, "It's none of the public's business what I do." J. P. Morgan said to another reporter, "I owe the public nothing." William H. Vanderbilt, when pressed for a statement about reduction of train schedules on his railroad, exclaimed to a reporter who talked insistently of the public interest, "The public be damned!" The businessman's belief in his right to secrecy was rooted in a tradition dating back to the medieval guilds. But it was dangerous to rest on real or supposed rights, in view of popular antagonism toward big business, an attitude equally traditional.

A clash between the two traditions was inevitable, and it took place in the "muckraking" era (see MUCKRAKERS). A series of harrying congressional investigations of big business accompanied the muckrakers' attacks. "We are passing through a reform—yea, a revolutionary period in business affairs," Henry Clews wrote in the *Annals* of the American Academy of Political and Social Science for July 1906. He called on banking and insurance interests to drop their policy of secrecy, which, he said, was "obviously in defiance of public sentiment."

Also in 1906 Ivy L. Lee, a former newspaperman, was appointed publicity adviser to a group of anthracite operators who had aroused the anger of the press by their haughty attitude in labour disputes. Soon after Lee's appointment it was announced that the operators would supply the press with all possible information. Lee then sent to city editors a declaration of his policies, in which

he said: "This is not a secret press bureau. All our work is done in the open. . . . If you think any of our matter ought properly to go to your business office, do not use it." Retained by the Pennsylvania Railroad the same year, Lee made information concerning accidents available to the press for the first time. In 1921 his firm issued its bulletin, previously called *Notes and Clippings*, under the title of *Public Relations*. In 1923 Edward L. Bernays published *Crystallizing Public Opinion*. This book, describing publicity functions and techniques with an emphasis on social responsibility, did much to popularize the term public relations and to gain recognition for specialists in the field.

Meanwhile, men were being hired in the service of the federal government under such titles as "director of information," "editor," and "supervisor of information research," which evaded a congressional act of 1913 forbidding the spending for "publicity experts" of any funds not specifically designated by Congress for that purpose. In Britain, the Empire Marketing Board began using large-scale publicity for the promotion of trade in 1924. *Report on the British Press* said of the Empire Marketing Board that "before its demise in 1933 it had established the archetype of Government Public Relations Departments." In Britain, as in the United States, appointment of public relations directors by government departments during World War II was the prelude to increased postwar emphasis on public relations. One indication of the greatly heightened interest in the United States was the fact that many colleges were adding courses in public relations to their curriculums. Boston University established the first school of public relations in 1947.

Philosophy of Public Relations.—Though early parallels can be found for every basic phase of public relations, as an organized activity it represents a major change in the philosophy of business—the recognition of the ultimate authority of public opinion. The basic purposes of a public relations department are the establishment and maintenance of good will. Obviously, the more the organization does to merit this good will, the easier the task of the public relations director will be. When he invites public attention to his company in connection with some attractive phase of its activities, he cannot be sure of limiting the interest of the press or public to that particular area. The efficient public relations executive therefore works for the elimination of policies that he believes to be open to criticism.

The public relations director or consultant frequently needs a high degree of persuasiveness in order to gain a hearing for a long-range point of view in councils concerned with immediate commercial objectives. In order to be an efficient representative of his company he must also be a representative of the interests of its employees, of the local communities in which it has factories, of the retailers who distribute its wares, of the consumers who buy them, and of the public at large. It is not necessary for him to be an altruist in order to do this; he need only realize that it is easier to eliminate sources of irritation than to justify them.

Publicity and Advertising in Public Relations.—When a policy has been set and the public relations representative is seeking publicity for it in news media, he must put his reliance not on techniques of persuasion but on his judgment as to what constitutes an acceptable story. A story with intrinsic news value, simply and clearly presented, usually receives an objective hearing. Public relations departments thus are usually watchful for such publicity opportunities as anniversaries that may be of local or general interest, public events in which an official of the company may logically participate, incidents involving celebrities, and developments susceptible to treatment as human-interest stories. In the handling of adverse news, such as that of accidents, the harm is minimized by candid answers to inquiries.

Creation of news events has become an important factor in the public relations programs of trade groups. For example, a public relations consultant, acting for a group of soap manufacturers anxious to combat a statement by cosmeticians that soap was bad for the skin, advised formation of a cleanliness institute. This was not a dummy organization; it actually conducted a cleanliness campaign, welcomed in public schools, and received widespread publicity. On another occasion a public relations

counsel initiated soap sculpture contests on behalf of the industry, a type of oblique publicity found to be of great value. Similarly, when the National Cotton Council was faced with competition from paper bags as feed containers, its public relations department sent representatives to show farm wives how they could convert cotton feed bags into attractive dresses. Photography editors were attracted by the idea, which proved an effective stimulant for the sale of cotton.

As some large corporations became aware of the importance of courting public opinion, they began to supplement their publicity efforts with a new type of advertising—one that was not designed to gain business but to clarify their policies and improve their relationships with their employees, the local community, and the public at large. The Bell Telephone Company was active in this field as early as 1908; after World War II the company, unable to fill the demand for new installations, published a series of advertisements explaining why delays were unavoidable. The flood of complaints subsided to a point below the prewar average.

In public relations advertising by management in connection with labour disputes, a temperate policy, anticipating the day when the strike will be settled, has been found to be wise. During a strike at a General Electric plant in Bridgeport, Conn., in 1946, the company presented the view that wages must be geared to production, but avoided strident controversy; one advertisement was devoted to announcing that the strikers' insurance under the company's employee plan was being kept in force.

Industrial Relations.—Winning the goodwill of its employees is one of the major objectives of every industrial organization. The morale of a factory's workers affects the quantity and quality of production; the company's position in competing for skilled workers; its popularity or unpopularity in the local community, which in turn affects the treatment it receives from the municipal administration; and its reputation as a whole. No public relations technique can offset substandard wages or unsatisfactory working conditions. However, even a policy that is intended to be equitable may run into trouble if administered in impersonal, bureaucratic fashion. Accordingly, an efficient public relations director makes a strong effort to keep management sensitive to human values. Employees are informed of new developments promptly, before rumours have time to spread; they are encouraged to submit complaints as well as suggestions; advance proofs of institutional advertising are posted on factory bulletin boards; facts on the company's earnings and prospects are made available; in some organizations, regular jobholders' meetings, similar to stockholders' meetings, are held; issuance of publications for employees is a standard practice. (See further INDUSTRIAL RELATIONS.)

Scope of Public Relations Departments.—Almost every form of the printed and spoken word, and of photography, is used in public relations work. Following are routine public relations responsibilities: issuing news releases to newspapers, radio stations, trade journals, and magazines; arranging press conferences; answering queries from the press and public; preparing text and illustrative matter for public relations advertising, pamphlets, employee magazines, manuals for the training of new employees, reports to stockholders, and form letters; planning documentary motion pictures, recorded television programs, filmstrips, lantern slides, charts, and recorded talks; planning and publicizing exhibitions and "open house" days at factories; and planning research surveys for gauging the opinions of employees, customers, or the general public. In addition, in cases where the product of the company is expensive, such as an automobile, the public relations department may prepare a magazine for distribution to listed customers; some corporations issue special magazines for their stockholders. Public relations directors of trade organizations, long-established companies, and various institutions also have arranged for the publication of books, sometimes by well-known writers, telling the history of the organization or industry; these are usually placed on sale through normal channels but often are subsidized to assure the publisher against loss. Some organizations employ not only a public relations director, with a staff under his supervision, but also a public relations consultant, to provide an outside point of view on questions of policy.

Most public relations work involves a combination of logical and psychological methods. Exaggeration and distortion defeat their own purpose; but often it is possible to switch from an unpopular concept, expressed in a standardized term, to a popular or at least an acceptable one, without doing violence to truth. An illustration of this is the substitution in public relations advertising by labour unions of the term "union security" for "closed shop." Another is the use by manufacturers of the term "billiards" instead of "pool," which had taken on the connotation of shabby pool rooms.

Much specialization has developed in public relations work in areas such as banking, agriculture, education, philanthropy, etc. Also, many public relations workers specialize in the use of specific media, such as audiovisual materials or stockholder reports.

PUBLIC SCHOOL (GREAT BRITAIN). The chief independent, or privately endowed, secondary schools in Great Britain traditionally have been known as public schools. The term includes not only the schools of ancient foundation such as Eton, Harrow, and Winchester, but also schools of comparatively recent creation such as Clifton College in Bristol, Cheltenham, and Marlborough. See EDUCATION, HISTORY OF: *Great Britain and the Commonwealth of Nations: Secondary and Technical Education to 1900*; SECONDARY EDUCATION. See also ETON; HARROW; etc.

PUBLIC UTILITIES, a designation for a special grouping of industries legally "affected with a public interest" and conducted under government regulation. They occupy an intermediate position between state services or public works, which are administered as public functions and hence supported by taxation and the variety of business undertakings usually included under the heading of competitive private enterprise. Public utilities properly so-called, need not be privately owned. In almost every country a varying number of them, such as telephones and railroads, are owned and operated by the state. But these publicly managed enterprises, instead of looking to the state for financial support, sell their services to the general public (see also PUBLIC ENTERPRISE). Both publicly and privately owned utilities set their services at prices which are governmentally fixed. This aspect is the most important part of the process known as public-utility regulation.

Although economic and technical evolution is continually changing the character of these industries, besides creating new ones public utilities may be classified according to the generalized function which they perform in economic life. The main public services supplied through public utilities are: (1) transportation (common carriers), including railroad, highway and local transit; oil and gas pipelines, waterways, and airlines; (2) communications—telephone, telegraph, radio, and television; (3) power, heat and light—gas and electric; (4) community facilities for water, sanitation, and irrigation.

Historical Background.—Public utilities are closely associated with developing civilization, supplying wants so fundamental for communal living that government has at all times subjected them to some measure of control. With the growth of trade in ancient empires facilities providing transport and communication were set up. The governmentally maintained highway system of the Roman Empire and its many aqueduct systems are celebrated ancient public works. In the more populous ancient cities, systems of sanitation also became a necessity. With these needs came the recognition that services used collectively should be supplied by the state. Public utilities thus began as state functions. By the Middle Ages most of the ancient public utilities had declined or virtually disappeared. By slow stages, upon the manors and in the medieval cities, these public facilities again appeared. Of great importance in British and American legal history is the fact that out of the economic and legal relationships of feudalism there arose the concept of a "public calling" upon which the modern policy of public-utility regulation is based.

The modern national state gradually supplanted the elements of the feudal system of social control. The expanding domestic system of manufacture was displacing the guild and manorial system of production; foreign trade was growing. National systems of transport involving highways and canals were undertaken and the regulation of utilities became national rather than local.

The greatest impetus in the expansion of public utilities came with the Industrial Revolution. Under the stimulus of the factory system cities grew as never before, creating a municipal need of systems of water supply, sanitation, transport, communication, illumination, and power. But the philosophy of *laissez faire* was not fertile ground for the extension of public functions. While the rapid industrial changes intensified needs, the tendency was to give greater scope to private enterprise.

However, the evils of a system which left the supply of basic economic wants to private industry insufficiently regulated by government became too flagrant to be overlooked. Beginning about 1840 the revolt against *laissez faire* doctrines caused an enlargement of the scope of governmental action. The older public utility services were continued for the most part as public enterprises, while the newer services were supplied by private initiative under some form of public supervision and assistance. Thus emerged the modern notion of a public utility, distinct from strictly governmental services and strictly private business.

Economic Characteristics.—Developments in the engineering arts bring changes in economic organization. For instance, lighting of the home was transformed first from a self-sufficient household industry (as the making of candles) to a commercial competitive industry (the supply of candles, lamps, whale oil, and petroleum), and then to monopolistic industry (electric lighting), where central sources of supply satisfy all demands. Perhaps the most significant economic conclusion founded upon these changes is that the social value of public-utility services is increased and the economic cost of rendering them is reduced by a consolidation of enterprises. The individual user of water in urban centres no longer had to depend for his supply upon his own well, nor did he have to buy from one of several competing sources. He resorted to a single common source of supply along with other users. This was found to be more convenient, economical, and, indeed, the only practical solution. But this process of integration of supply was long and in some public service industries it was not completely realized. The tendency toward monopoly, however, whether the result of a competitive struggle or brought about by legislation, became a fundamental characteristic of public utility business.

Every public utility must be in possession of the natural resource upon which that industry is based. A gas or electric company must have possession of sites for the location of its works; a transportation company must have rights-of-way and terminal sites. These properties must have strategic locations. Limitation in the choice of this agent of production tends to make the cost of acquiring or leasing these facilities greater than it would be if the industry had a wider range of choice. Furthermore, utilities must make allowances in advance for probable increase in the required capacity. For these reasons utilities are provided with the governmental power of eminent domain which makes possible the compulsory sale of private property. Thus the law recognizes that, socially considered, these properties are being put to the highest uses of which they are capable.

Fixed Capital.—The typical public utility—railroad, telephone system, or electric power plant—serves an area of the economy where duplication of facilities is regarded as economic waste. Public-utility facilities entail a much higher investment of fixed capital in relation to sales or receipts than is required for industry in general. The liquid capital solicited from investors is converted into durable, specialized structures and equipment. The facilities must be designed to insure the regular and adequate supply of the service for which the franchise is granted. At the same time the service must be produced and sold on terms that will provide a return on the invested capital sufficient to permit adequate maintenance and replacement, and to attract additional investment funds for expanding demand. This reconciliation of the interests of the enterprise with the public interest is a basic objective of govern-

ment supervision of public utilities.

The expansion of metropolitan areas and the interdependence of communities in the use of joint facilities are reflected in the enlarged scope of public-utility operations. These developments have accompanied technological improvements in which fuller advantage is taken of the economies of size. This is exemplified in the utilities supplying power, where economical operation is secured by combining power sources into so-called super power systems in which the power stations are interconnected by transmission lines. The reciprocal sale of power from one system to another is thus possible when the common reserve serves a large area. The cooperative action insures the utilization of surplus power, safeguards the service from interruptions, and secures the advantages of full use of investment by building up the diversity of use.

Availability of Utility Services.—All public utilities must stand ready to supply their services on demand, and utilities may be divided into two classes according to the method by which they meet this situation. The first class, or service type, comprises the utilities that cannot store their services but must adjust to demand variations by maintaining productive capacity equivalent to peak demand, with a resulting tendency toward increased cost of operation. This includes electric, telephone, telegraph, and transportation utilities, as well as the postal service. The second class, the product type, consists of utilities that may be stored, so that output can be uniform and excess production in periods of slack demand set aside for use when customer requirements are high. The ability to limit producing capacity to the equivalent of average demand tends to lower costs, but storage requirements are an added cost item.

The additional cost of being ready to meet all demands without delay must be taken into account in determining the conditions under which the public utility may operate and the rates it must charge to provide reasonable earnings. The problem is to balance the interests of the management and investors with the interest of the community in obtaining the most efficient service.

REGULATION IN THE UNITED STATES

A common legal background of public-utility regulation both in the United States and in Great Britain is disclosed by the decision of the U.S. Supreme Court in *Munn v. Illinois* (94 U.S. 113 [1877]). The *Munn* case involved the validity of an Illinois statute fixing maximum rates for storing grain in elevators. *Munn* had been engaged in the elevator business since 1862, long before the enactment of the statute, and had been in the habit of charging rates fixed by agreement among the elevator owners in Chicago, Ill., and had continued to charge these rates although they were in excess of those fixed by the act. *Munn* was convicted and fined in the state courts but appealed to the U.S. Supreme Court upon the ground that the act violated the 14th Amendment in that it deprived him of his property without due process of law.

Chief Justice Morrison Waite, in upholding the validity of the statute, said in substance that under the circumstances in which the elevators were being operated in Chicago (i.e., standing in "the very gateway of commerce and taking toll from all who pass") they had become business "affected with a public interest and had ceased to be *juris private* only." This was not his own language but was quoted from Lord Chief Justice Matthew Hale who had penned it about 200 years before in England. This legal doctrine, he said, had been a rule of the law of property ever since; that under this rule and in exercising the police power of the state, "it had been customary in England from time immemorial and in America from its first colonization to regulate ferries, common carriers, hackmen, bakers, millers, wharfingers, innkeepers, and so forth," and to fix maximum charges. In further explanation of this "public interest" doctrine, the court said that private property is being used "in a manner to make it of public consequence, and affecting the community at large. When, therefore, one devotes his property to a use in which the public has an interest, he, in effect, grants to the public an interest in that use, and must submit to be controlled by the public for the common good, to the extent of the interest he has thus created. He may withdraw his grant by dis-

continuing the use; but, so long as he maintains the use, he must submit to the control."

In a later case (*Charles Wolff Packing Co. v. Court of Industrial Relations of the State of Kansas*, 262 U.S. 522 [1923]), Chief Justice William Howard Taft of the U.S. Supreme Court gave further precision to this "public interest" doctrine by saying: "In a sense, the public is concerned about all lawful business because it contributes to the prosperity and well-being of the people. The public may suffer from high prices or strikes in many trades, but the expression 'clothed with a public interest' as applied to a business means more than that the public welfare is affected by continuity or by the price at which a commodity is sold or a service rendered. The circumstances which clothe a particular kind of business with a public interest, in the sense of *Munn v. Illinois* and other cases, must be such as to create a peculiarly close relation between the public and those engaged in it, and raise implications of an affirmative obligation on their part to be reasonable in dealing with the public."

Between 1923 and 1934, and particularly during the depression years, a series of cases involving the constitutionality of price regulation was decided by the United States Supreme Court. With a dissenting minority of liberals, the court ruled against the regulation of the resale price of theatre tickets in New York City and of the fees of private employment agencies in New Jersey. Without dissent it forbade the regulation of the retail price of gasoline in Tennessee. A divided court decided against the regulation of competition among artificial ice plants in Oklahoma. This negation of the extension of regulatory power was halted in 1934 when New York was upheld in its efforts to stabilize the fluid milk supply industry and rescue it from price-cutting tactics through the fixing of minimum prices by a milk control board. The seeming confusion behind these contradictory opinions can be explained by noting that the trend was in the direction of extending the use of the police power in the interests of public health, safety, morals, and the general welfare, while the hard core of public-utility regulation in the interests of monopoly control continued without abatement.

Obligations of Public Utilities.—The affirmative obligations upon public utilities arising out of their peculiarly close relation to the public are usually spoken of as that system of rights and duties which constitutes the law of public service undertakings. Briefly, this law places upon a public utility the extraordinary duty to render reasonably adequate service to all who apply. It is required to serve them up to the limit of its capacity, with capacity being defined as the limit of profitability. It may not let customers' wants go unsatisfied. Nor may it attach unreasonable conditions to contracts for service so as in effect to negate its duty "to serve all comers." Furthermore, it must serve without discrimination all customers similarly circumstanced. Finally, a public utility must observe more than ordinary care in the rendition of service in view of the dependence of the public upon such service and the hazards associated therewith. On the other hand, the same law concedes a public utility the right to collect a reasonable price, to render service subject to reasonable rules and regulations, and to withdraw service under prescribed conditions after giving notice to customers. While customers are given the right to demand that a public utility live up to its duties, they are, on the other hand, required to accept reciprocal obligations formally imposed by the regulatory body or implicit in the franchise.

Economic and Legal Determinants.—In determining whether a given industry is subject to this coercive law of public utility the courts have adopted certain practical tests of both a legal and an economic nature. The economic tests look to the presence of elements of natural monopoly in such number and strength that competition cannot work successfully. The power of the state will be used either to regulate industries so as to restore equality of bargaining power by maintaining competition and controlling competitive practices, or used to promote the inherent trend toward monopolistic organization by conferring upon such industries legal monopolies and then controlling their economic relations.

From an economic point of view it is clear, therefore, that the concept of a public utility is made up of two ideas: (1) the idea of monopoly; and (2) the idea of common necessity. Both must be present in order that an industry may become a public utility. Neither alone will suffice. The supply of housing facilities is a necessary economic function, and when it is furnished upon a competitive basis the customer is not coerced. But when, in emergencies such as the acute housing shortage (see *HOUSING*) during World Wars I and II, the consumer is forced to bargain for a necessity under conditions of temporary monopoly, the courts will uphold the regulation of rents. Yet the character of regulation will be such as to enable the industry to reach normal condition. The emergency having passed, as building operations are resumed competition again sets in and the reason for regulation disappears. The housing industry therefore represents a borderline case which, nevertheless, ought not to be classed as a public utility under normal conditions.

When freedom of choice is seriously restricted—that is, when the coercion residing in private property makes itself felt as a monopolistic power—public interest arises in proportion as equality of opportunity to choose is restricted, provided that the wants supplied are recognized as a common necessity. The concept of public utility thus becomes a legal instrumentality to achieve an improvement of the standard of life. In a society which is accustomed to look to governmental initiative for the supply of common needs, the facility will be supplied as a public function. On the other hand, a society which is distrustful of the state will leave the supplying of such common needs to a private agency under a franchise privilege, not as a matter of common right, but as an agency of the state.

Since the law had long recognized the rights and duties of public utilities, this legal conception attained a certain fixity in the form of legal rules. But the number and kind of industries that may be subjected to these rules is not fixed. It may be said that the legal notion of public utility is that of a fixed concept with a changing content. The industries at any time recognized as "clothed with a public interest" are not necessarily the industries which may legally be classified as public utilities at another time. The industrial and political situation as mirrored in public opinion will determine: (1) the number and kind of industries classified as public utilities; (2) the elaboration of the system of rights and duties which make up the institution; (3) the regulating agencies and instrumentalities employed (whether the legal rules and decrees of courts or the charters, special franchises, and statutes of legislatures); and (4) the subordinate administrative standards which are evolved in practice. The trend in the development and application of the institution will be a resultant of the amount of social inertia, of the pressure of the economic environment and of the influence of intellectual progress.

Forms of Regulation.—Regulation in the United States has been accomplished in three distinct ways: (1) judicially by means of suits at law where the common-law duties and rights of public utilities are applied in specific cases; (2) legislatively by means of corporate charters or special franchises; (3) legislatively by means of the police power of the states or its federal equivalent, the power of congress over interstate and foreign commerce. Judicial regulation is the oldest and constituted almost the only form of control during the first half of the 19th century. Legislative regulation later largely supplanted judicial regulation, but the latter remained in the background as a potential agency which might become active again if legislative regulation should disappear. The function of the judiciary by 1898 had been restricted to the review of legislative and administrative acts.

Legislative regulation by means of the charter or special franchise was the next to be tried. The special franchise is now generally conferred under constitutional or statutory authority by local governments. The method of special franchise regulation is applied to so-called local public utilities, furnishing telephone, gas, electric, water, and transportation services in local communities.

The weakness of legislative regulation by charter was that the maximum rates therein provided were largely in excess of those

actually charged by the companies. Competition of carriers with each other, the decreasing unit cost of operation on account of increased utilization of plant capacity, the decline in the level of prices after the Civil War, and continuous improvements in technique made it possible for utilities to charge rates below those fixed in the charters. The failure to provide adequately for financial and accounting control enabled the issuance of more stock and the padding of investment accounts, thus vitiating the control based upon net income. Special franchise regulation followed the procedure applied in the case of carriers. Maximum rates were fixed in the local franchise of telephone, gas, electric, and water undertakings. These maximum rates soon became obsolete because the growing business of the companies required more complex and flexible rate schedules. Moreover, the companies began to appreciate that increased earnings, both gross and net, could be secured by means of rate reductions.

When state legislatures in the case of national carriers and local councils in the case of local utilities attempted to adjust these rates downward, they were met by the objection that the change would violate a contractual obligation and confiscate the property of the companies. Only when the franchise was silent on rate questions or when the power to alter, amend, or repeal the terms of franchises was reserved, could the power to regulate rates or service be exercised by state or local legislatures. Another evil that had crept into the administration of public utilities as a result of the ineffectiveness of rate control was discrimination in rates. This was also induced by the fact that competition had never been entirely eliminated. Added to this, in the case of the limited term franchises of local utilities, was the growing insecurity of tenure. Failing to obtain a renewal the properties would be worth only their scrap value. Often there were no provisions for public purchase or for purchase by some other grantee at the end of the franchise period. The inducement was too great, therefore, to manipulate operations so as to enable investors to recoup their capital out of earnings.

About 1870-80 a policy was adopted of fixing rates by direct legislation. Legislatures realized that statutory regulation should be general rather than specific; that the rate and service problems require continuous attention; that the subject matter of statutes should be the laying down of principles and standards; that the new policy of continuous regulation required an effective agency, sufficiently informed by experience to carry legislative standards and principles into effect. This agency is the modern administrative commission, acting as an agent of the legislature. All states set up regulatory commissions with varying jurisdictions. The first federal agency to regulate a public utility was set up in 1887 to control the interstate commerce of the railroads. As new public-utility industries arose, additional agencies were established or the jurisdictional scope of existing ones broadened. Their authority was strengthened as the need for more adequate control became apparent. Federal regulation in the mid-1960s covered the three major fields of transportation, power, and communication. Control over transportation is effected through: (1) the Interstate Commerce Commission, established in 1887 to regulate the railroads, and its jurisdiction being extended to cover pipelines other than water and gas (1906), motor carriers (1935), interstate and coastal water carriers (1940), and freight forwarders (1942); (2) the Federal Maritime Board and the Maritime Administration, set up in 1950 (stemming from the U.S. Shipping Board of 1917) to regulate offshore shipping; and (3) the Civil Aeronautics Board, created in 1940 (as a reorganization of the Civil Aeronautics Authority of 1938), with jurisdiction over air carriers. Since 1958 it has shared jurisdiction with the Federal Aviation Agency. Authority in the area of power is exercised by the Federal Power Commission (organized as an independent commission in 1930), which regulates hydroelectric projects and the transportation and sale of electric power and natural gas. Communication by wire and radio, both interstate and with other countries, is regulated by the Federal Communications Commission, established in 1934. In 1935 the Securities and Exchange Commission was empowered to regulate transactions in securities, including those of public utilities.

With the exception of the Securities and Exchange Commission, which is concerned only with financial ownership, these agencies are in general charged with fostering adequate service at reasonable rates. Their powers vary according to the nature of the utility involved but, in addition to regulation of rates, commonly cover such matters as licensing of operations, ruling on maintenance of services, promoting safety regulations, and passing on intercompany agreements. The administrative commission applies the common-law rule of reasonableness to the concrete facts in each case and names the particular rate or service regulation deemed appropriate to the circumstances.

Regulation of all public utilities was hampered by the insistence of the courts after 1898, when the epoch-making case of *Smyth v. Ames* was decided, upon defining the basis for rate-making which commissions might use. The major conflict was over the weight to be accorded reproduction costs as compared with actual original costs in the determination of the "fair value" of the investment. With the rise in the levels of prices, particularly after 1914, commissions were inclined to use the standard of actual investment costs while the utilities were contending for reproduction costs. In a series of decisions culminating in *McCardle v. Indianapolis Motor Co.* (272 U.S. 400 [1926]) the courts upheld the position of the utilities. But the courts receded from this extreme position after the depression set in and in *Federal Power Commission v. Natural Gas Pipeline Co.* (315 U.S. 575 [1942]) conceded that the particular formula of rate determination was within the discretion of commissions, so long as the result was not arbitrary or confiscatory. The *Hope* case (*Federal Power Commission v. Hope Natural Gas*, 320 U.S. 591 [1944]) further strengthened the position of the commissions by specifically rejecting "fair value" as the determining factor in rate-making, thus leaving commissions free to take into account "prudent investment" in fixing rates designed to provide adequate earnings and attract new capital.

Late in 1960 the U.S. government made public a report on the federal regulatory commissions prepared by James M. Landis, former dean of the Harvard Law School and former chairman of the Securities and Exchange Commission. The report was particularly critical of the commissions that regulated public utilities and cited the Federal Power Commission as "the outstanding example in the Federal Government of the breakdown of the administrative process." The report charged that the commissions were smothered in red tape, beset by lobbyists, and years behind in their decisions. Largely as a result of this report, Congress revived a law giving the chief executive authority for a period of four years to submit to the legislative branch proposals for reorganizing the regulatory agencies. (M. G. G.; A. D. H. K.)

REGULATION IN EUROPE

In western Europe many public utilities are nationalized, while some are administered by mixed companies financed with both public and private capital. Nearly all the telephone and telegraph systems are publicly owned and operated, as are most of the railways. Electricity was nationalized in many countries after the development of hydroelectric power; the undertakings were usually brought under the complete control of state, provincial, or municipal authorities, but in some countries they were left partly under private ownership, as in the case of gas. Irrespective of ownership, public utilities are as a rule subject to a measure of public accountability and to statutory control, particularly of standards and prices. With the trend toward larger units of operation, there is a tendency for centralized administration and control to replace the local ownership of utilities, and cooperation is fostered where ownership remains diversified.

Great Britain.—In Great Britain before World War II the railways were privately owned though subject to considerable regulatory control, but a great number of other public utilities, including much local road passenger transport, water supplies, and gas and electricity undertakings, were owned and operated by local authorities or by joint public boards. The remainder were privately owned. Many which had been started with private capital were subsequently acquired by the local authorities, but

in the case of transport the municipalities were frequently responsible from the start. Thus one-third of the gas, four-fifths of the water supply, and two-thirds of electricity distribution were in the hands of the municipalities, while the wholesale distribution of electricity over the "grid" was the responsibility of a public board. Before the war the municipalities tended to acquire privately owned undertakings, and in most cases those owned by companies were subject to the local authorities' option to purchase on the expiry of the franchise or at fixed dates. Thus the competition resulting from diversified ownership tended to be replaced by local monopolies, and with their establishment came the need for stricter regulation to protect consumers and to maintain standards. Public utilities were exempt from the Companies Acts, which permitted joint stock organization of all concerns complying with the terms of these acts; they had therefore to be established by the lengthy process of private bill legislation, separate acts conferring franchises on a monopoly basis and determining the conditions which were to regulate the operation of each undertaking. Sometimes, however, special legislation to establish each public service undertaking was dispensed with and general powers were granted to enable the appropriate government department to issue provisional orders after due inquiry. Nevertheless, legislative control was retained, for confirmation of the provisional orders had to be obtained from Parliament.

Public and private utilities were both subject to a considerable number of statutory regulations, but the former enjoyed somewhat greater freedom than the latter, particularly with regard to charges. Such regulations fell into three main categories. First, there were safety measures to protect the general public and provisions to safeguard the rights of property owners whose land was compulsorily acquired, as also the rights of the subscribers of capital. Second, minimum standards of quality for the services provided were laid down. Third, there were price controls to protect the consumer against exploitation by monopoly. The British system of regulation was, accordingly, comparable to a certain extent with the system of charter or special franchise prevalent in the United States. Typical laws were the Gas Meters Clauses Act of 1871 and the Gas Regulation Act of 1920, the Electricity (Supply) Acts of 1919, 1922, and 1926, and a whole series of railway acts. The crucial point of all these was the regulation of rates. In the case of private gas companies, for instance, the initial method of control, after a brief period of competition, was the so-called revision system. Maximum rates and maximum dividends were fixed in special acts, but the power to reduce rates was given to the Court of Quarter Sessions. Later, an alternative method, the system of sliding scales, was devised, but its adoption was optional. A standard selling price for gas and a standard maximum rate of dividend having been established, it was provided that the dividend might vary in inverse ratio to the rate of charge. In the case of electricity it was usual to fix maximum prices that could be charged, but rates could be below the ceiling. Railway rates were subject to the authorization of a quasi-judicial body, the Railway Rates Tribunal.

Water was supplied by local boards, municipalities, and private concerns. Here again the trend, even before World War I, was toward larger units. For instance, the Metropolitan Water Board was established in 1903 to take over the eight companies providing London with its water supply. It was a statutory body with a board of management representative of the local authorities, other users, and the river conservancy boards. Like those of other undertakings, its maximum rates were fixed by statute. Despite this trend toward regrouping in larger units, a great many small local authorities and private concerns continued as water suppliers.

Both public and private local road passenger transport undertakings, practically all enjoying monopoly of operation in their area, were subject to a licensing system under the Road Traffic Act, 1930. Regional traffic commissioners were appointed and made responsible for licensing public service vehicles within the conditions laid down by this act with a view to regulating competition between road and rail and avoiding the provision of excessive transport facilities. These aims were to be achieved by proportioning the number of vehicles to traffic requirements and by the

regulation of fares, services, and frequencies. The safety of passengers was protected by the establishment of standards for the construction, use, and maintenance of vehicles and by the licensing of their crews. Under the Road and Rail Traffic Act, 1933, a licensing system was also introduced to regulate road haulage vehicles operating for hire or reward (but not those carrying the goods of their owners).

In general, communications facilities have been publicly owned since the 17th century, when the postal service became a government monopoly. Telephone and telegraph services were taken over by the state after their initial development by private companies; exceptionally the city of Hull operates its own local telephone service. Cable and radio services were merged compulsorily between World Wars I and II, and were finally nationalized after World War II. The British Broadcasting Corporation (formerly the British Broadcasting Company) was established in 1927 as a public corporation under royal charter with a monopoly of sound broadcasting, which it retains. It also pioneered television before World War II but a second public corporation, the Independent Television Authority, was established in 1954, by act of Parliament, to provide commercial television in competition with it, through the medium of private program contractors.

Between World War I and World War II, larger public-utilities units were formed through government-imposed amalgamations. Thus the Railways Act, 1921, compulsorily merged the railways into four main-line companies and fixed their standard earnings, which the Railway Rates Tribunal was to take into account when authorizing charges. Similarly, the Electricity (Supply) Act, 1919, was intended to bring about mergers and reorganization in the electricity industry in order to facilitate the production of cheaper electricity by larger units. The act established an Electricity Commission of five members appointed by the minister of transport, and to this were transferred many of the regulatory powers previously vested in government departments. Inadequate mandatory powers for the commission, and insufficient cooperation from the electricity undertakings, were largely responsible for the act's failure. It was accordingly superseded by the Electricity (Supply) Act, 1926, which established the Central Electricity Board. This public corporation was charged with constructing a national grid of main transmission lines over which electricity generated at selected power stations could be supplied wholesale to local distributors for retail to consumers. Local distributors remained unchanged until April 1, 1948, when, under the Labour government's nationalization program, both generation and distribution of electricity were transferred to public ownership. The British (later Central) Electricity Authority became responsible for generation and the grid, and its 14 (later 12) area boards for local distribution in England and Wales. In Scotland responsibility was transferred to two public boards independent of the central authority. Following the report of the Committee of Inquiry into the Electricity Supply Industry in 1956, legislation was enacted to bring about certain major changes in the administrative and operational structure of the industry. The Central Electricity Authority was abolished and replaced by the Central Electricity Generating Board and the Electricity Council. The board's main function was the generation of electricity and its supply in bulk over the grid to the area boards, while the council acted as a forum for the formulation of general policy, also having certain specific functions with regard to finance, research, and industrial relations. Responsibility for the development of nuclear power was entrusted to the Atomic Energy Authority, which established the world's first atomic power project, from which electricity was fed into the grid. But the responsibility for placing contracts for and operating nuclear power stations devolved upon the generating board.

Under the Gas Act, 1948, control of the manufactured gas industry, which had been slower to integrate and which comprised more than 1,000 municipal and private concerns, was transferred to the Gas Council and its area boards on May 1, 1949. The council had mainly supervisory functions, as the boards were made responsible for both production and distribution.

After a government White Paper outlining a national water

policy, legislation was enacted to rationalize the industry by regrouping and by appointing regional bodies to assist in the conservation of water resources and the joint use of water supplies. Despite these steps, water was still supplied by nearly 1,000 separate undertakings, of which about 90% were publicly owned (80% by local authorities and 10% by water boards), the remainder being water companies.

Railways, which had been under government control throughout World War II, were not returned to their former owners but nationalized by the Transport Act, 1947; together with their ancillary services, which included certain of the road passenger undertakings. Also nationalized were certain docks and harbours, inland waterways, and long-distance commercial road haulage. All were brought within a single undertaking for which the British Transport Commission (BTC) was made responsible as of Jan. 1, 1948. Previously most of the canals had been privately owned, but two in Scotland were already publicly owned and the Manchester Ship Canal was a mixed undertaking; the BTC did not acquire the latter. Most docks and harbours were run either by public boards or by representative trusts, and these were left untouched. Of the remainder, some were operated by the railway companies and some by private companies, and most of these passed into the hands of the BTC. Long-distance commercial road haulage was in private hands, although there was a considerable railway interest in it. Road passenger transport was operated chiefly by the municipalities. However, some small companies operated local services, and mergers had resulted in a few large companies which operated all the long-distance transport. The railways had a considerable share in these large companies and their holdings were acquired by the BTC, which afterward extended its interests still further. Following the report of a committee of inquiry into inland waterways in 1958, an Inland Waterways Redevelopment Advisory Committee was set up to draft plans for the disposal of canals no longer used for navigation. Under the Transport Act, 1953, a large section of road haulage operating for hire or reward was denationalized, but under the Transport (Disposal of Road Haulage Property) Act, 1956, the commission subsequently retained a substantial proportion of it, including the nationwide trunking and parcels services. Under the Transport Act, 1962, the commission was dissolved, the railways, docks, and waterways became the responsibility of three separate boards, and the road haulage and road passenger undertakings and other ancillaries were transferred to a holding company.

In Great Britain government regulation of public utilities has evolved from statutory regulation of private and public concerns to direct ownership on a monopoly basis through public corporations, except in the case of water supply.

Continental Europe.—Before World War II public utilities in continental Europe were for the most part either publicly owned or operated by mixed companies, although in some countries there were a number of purely commercial concerns. Thus in France about one-third of the gas output was produced by undertakings owned and operated by the larger city councils, the remainder being in the hands of commercial companies. But, whatever the ownership of the services, statutory regulations controlled prices and quality and, in some cases, profits. Most railways, as for example those of France and Belgium, were run by mixed undertakings, with share capital held both publicly and privately. After World War II a number of concerns were nationalized and the remainder subjected to an increasing amount of control. In France, for instance, gas and electricity were nationalized and administered by public corporations under the supervision of a joint council responsible for the coordination of the two services. In some countries, although privately owned companies continued to operate with a large measure of independence, they worked in increasingly close cooperation among themselves so as to ensure the best use of available resources. Similar cooperation was developed between the private companies and the municipal and state-owned concerns, and in a few countries centralized control of day-to-day operations was introduced on a national basis. Similarly, throughout western Europe the trend was toward greater

cooperation between countries, particularly with regard to the exchange of electricity across frontiers; for example, a link was forged across the English Channel between the nationalized electricity industries in France and Great Britain. To these ends the Organization for European Economic Cooperation (subsequently the Organization for Economic Cooperation and Development), the Economic Commission for Europe, and the European Economic Community (Common Market) contributed substantially. In 1957 the European Atomic Energy Community (Euratom) was established to develop atomic energy for peaceful purposes within the European Economic Community. (E. A. J. D.)

PUBLIC WELFARE. This term has come into use, especially in the United States, to indicate governmental (i.e., public) social welfare programs, as distinguished from similar programs conducted by private, or voluntary, organizations (see SOCIAL SECURITY; SOCIAL WELFARE). A further distinction is sometimes made in which "welfare" connotes a program utilizing a needs test, as distinguished from a program of social insurance.

Public welfare programs that developed in colonial America and later in the states evolved from the Elizabethan Poor Law of 1601 (see POOR LAW: United States). Sole responsibility was placed on local (town or township and county) financing and administration of outdoor relief for the able-bodied poor and custodial care for dependent infants and young children, the handicapped or disabled and the aged in orphanages, almshouses, county homes, or poor farms. State governments did not begin to assume responsibility until the latter part of the 19th century when state agencies, often called departments of charities and corrections, were created. The first board of public welfare was created in Kansas City, Mo., in 1910, and in 1917 North Carolina and Illinois established state departments of public welfare along present-day lines. The movement spread slowly. The great depression of 1929 and the enactment of the Social Security Act in 1935 resulted in the establishment in every state by 1940 of a state welfare department with local units. Extensive revisions in the law were enacted by Congress in 1962 to open new avenues for making public welfare a more constructive instrument in preventing and reducing dependency.

Modern public welfare programs include public assistance to the needy, sometimes called "relief" or "welfare"; child welfare services; and services for the aged and other dependent groups. Some programs include certain aspects of juvenile delinquency or medical care, which in other instances are handled by correction or public health agencies.

PUBLILIUS SYRUS (1st century B.C.), a Latin mime writer contemporary with Cicero, chiefly remembered as the author of a collection of versified aphorisms (*sententiae*) extracted from the mimes probably in the 1st century A.D. Early incorporation

of non-Publilian verses and scribal distortions of authentic lines in these *sententiae* have considerably aggravated the labours of the textual critic. Modern editions contain more than 700 verses, alphabetically arranged; most of these are iambic senarii, some trochaic septenarii. Publius, who went to Rome as a slave from Syria, was soon manumitted. He defeated the veteran mime writer Decimus Laberius (*q.v.*), in a contest held in 45 B.C., when the latter was "invited" by Caesar to perform in one of his own mimes. Though Cicero—no unbiased authority, as Laberius had scored off him—deplored the tedium induced by performances of Laberius and Publilius, Seneca the Elder and Gellius praised him, and St. Jerome quoted a verse remembered from schooldays. Later, he was known to Shakespeare, and the motto of the *Edinburgh Review* (*Judex damnatur cum nocens absolvitur*; i.e., "The acquittal of the guilty condemns the judge") comes from him.

PUBLISHING. Publishing is the selection, reproduction, and circulation of written matter. It is older than both printing and paper, though in modern times it has come to depend upon both. Printing from blocks was invented in China some time before the middle of the 9th century; printing from movable type had been invented there by the middle of the 11th century. But at neither time was printing thought of or encouraged other than as an excellent device for avoiding the errors of transcription that often marked the work of even the best manuscript scribes and copyists. In Europe printing from movable type was introduced by the middle of the 15th century. But there, as in China, its major advantage over older methods of reproduction was thought to be the standardization of scripture and official texts. Neither in Asia nor in Europe was printing viewed at first as being useful in the wide dissemination of literature, learning, or political or religious discussion. As an instrument of publishing, printing had to fight its way. Eventually it became a great instrument of spiritual and intellectual development and of theological and scientific discourse. But the earliest reaction, which persisted for centuries, was one of opposition by church, government, university, and other powerful interests (such as the Brahmin caste in India) to its use in giving wide publicity to certain ideas and information. (See also **PRINTING: The History of Printing.**)

The Earliest Books.—Before the invention of printing and of paper, publishing was carried on by means of professional scribes or skilled slaves making transcriptions of manuscripts on papyrus or parchment (*q.v.*). Flourishing industries in Egypt under the Ptolemies and in the major cities of Greece and Rome produced papyrus or parchment rolls for inscribing the classics of ancient literature, religion, and law. Often under the Roman Empire, as under later Western kings, princes, parliaments, and presbyteries, censorship and intimidation controlled or attempted to control publishers' output, thus interrupting the continuous history of commercial publishing for long stretches. Yet these ancient enterprises were authentic prototypes of modern publishing houses. Their work consisted in selecting manuscripts for reproduction in quantity; taking the risks of compensating authors in advance of public sale for rights to their manuscripts; determining the size, price, and format of editions of different titles; and developing markets where such editions could profitably be sold. They were publishers in every modern sense of the word, even though their products had not taken the form of books (see **BOOK**).

Books in the form with which the world has long been familiar (i.e., made up of pages bound together at one side) had a long and obscure development of their own. By the 4th century the bound book had become moderately well known, at least among the jurists and the Christian writers of the later Roman Empire. Its first real vogue, however, was in Ireland two or three centuries later. The climax of the remarkable flowering of intellectual and religious spirit there was the Book of Kells, not infrequently mentioned, according to one authority, as "the most beautiful book in the world" (see **ILLUMINATED MANUSCRIPTS**).

To distinguish it from the old *volumen*, or "roll" (from which

the word "volume," often used interchangeably with "book," is derived), the early bound book was called a *codex*. The *codex* became the typical book of the Middle Ages, and theological *codices* were produced in large quantities especially in the monasteries of various church orders, which were the publishing centres of the day. *Codices* in law, medicine, rhetoric, and other fields of learning came from the rising universities which, in certain cities, early wrested control of the publishing industries from the church and the state. In such centres the secondhand market was as well known to medieval students as it later became to those of the 20th century. The difference was that the universities, as noncommercial publishers, strove to keep prices down for the students and thus encouraged the use of old copies. This practice also relieved the universities of the need to produce large new editions every year.

The *codex*, like the papyrus and parchment rolls that it replaced, was written entirely by hand. In the scriptorium or "writery" of the monastery, scribes toiled during the daylight hours (fear of fire from artificial light prevented work on books at night) copying page after page of ancient classics and the Bible, thus laboriously accomplishing the great task of preserving them. The scribe's work was then proofread, and titles and notes were inserted. If illustrations were desired, the book then went to the illuminator, after which it was ready to be bound. This procedure was not very different, in essence, from manuscript preparation in a modern publishing house—except that with modern printing and illustrating methods, these and related publishing tasks are performed only once for an edition of many thousands and not over and over again for every individual *codex* or book. (See **BOOK: Vellum and the Codex; The Medieval Book.**)

Printing and Publishing in Modern Europe.—Though the early history of publishing owes nothing to printing, Johann Gutenberg's invention of printing from movable type gave a great boost to publishing in Europe after the middle of the 15th century. Gutenberg probably was not the first European to use movable letter type successfully. After his epochal achievement, however, Mainz, his home in Germany, became the indisputable publishing centre of the continent, and Germany itself became the source and fount of subsequent printing and publishing developments in the Western world. Before 1500 about 30,000 books were printed in Europe; of these, more than two-thirds came from such great German centres of learning as Leipzig, Cologne, Basel, Nürnberg, Augsburg, and Strasbourg. More important, the German printers trained in these cities about 1460 introduced modern printing and publishing into Italy, where it played an important part in the spread of Renaissance culture and trade. Similarly the Germans carried the printing industry and modern publishing to France in the early years of the 16th century. (See **PRINTING: The History of Printing.**)

It was only then that a broadening of the lay market for books took place. In 1501 Aldo Manuzio designed the first books in small format that eventually replaced the huge, elaborate, and costly *codex*, just as the *codex* had replaced the awkward *volumen*. In succeeding decades, especially in France, much attention was given to typography, and names still commonly used for typefaces in the 20th century became well known from the work, for example, of Claude Garamond and Robert Granjon. A customer of both these typographical artists, Christophe Plantin (*q.v.*) was the most famous of the early printers who became publishers. Plantin, who fled from Paris in 1548 to escape religious persecution, settled in Antwerp, where he returned to the good graces of the church and the university, gaining from the Holy See the monopoly of publishing liturgical books for the Spanish Empire and late in life becoming printer to the University of Leiden, a great publishing centre of the time.

Though many early printers remained faithful to the church and to their princes, the publishing of printed works quickly became one of the major means of organizing radical opinion in the late 15th and early 16th centuries. This naturally led to reprisals against the new publishing industry, especially in Germany, and in self-defense the publishers and printers organized into independent corporations and guilds that lasted until the 19th century.

in many countries. Where printing and publishing was not shut down or forced underground, as was the case in Nürnberg and Augsburg early in the 16th century, it was controlled by other means. Thus in France as early as 1474 the independent printers were brought under the same licensing regulations by which the University of Paris alone had monopolized the work of the old scribes and the publication of their manuscripts. This was indeed a signal recognition of the rapid rise of the printer to publishing eminence; yet it was also an onerous burden to the new publishers who were out of sympathy with officialdom.

Official controls on the one hand and guild restrictions on the other impeded the development of printing and publishing for centuries. On the continent one result was the emigration of printers and publishers to England, where, from 1476 to 1536, it is estimated that two-thirds of all printers, binders, and stationers were aliens. But even in England from 1534, when the Stationers' Company, or guild, was first organized into the monopoly of all English book publishing, to 1709, when the first copyright act was passed in the reign of Queen Anne, there was constant harassment of publishers, which, in due time, was carried across the ocean to America as well. During this epoch, when some freedom of publishing, bitterly won, was challenged by new efforts at control, John Milton wrote his *Areopagitica* in 1644. (See also CENSORSHIP.)

In France control was more or less thorough until the revolutionary copyright law of 1793 freed publishing and printing from all existing monopolies. This freedom was short-lived, however, ending under Napoleon's First Empire and not restored until the Declaration of the Republic in 1870. French restrictions had a salutary effect on the publishing industries in the Netherlands and Belgium, where during the 17th and 18th centuries large editions of the works of Molière, Boileau, Voltaire, Rousseau, and others were issued clandestinely for the French market.

As is usual with excessively rigorous controls, they often were poorly enforced, and, as is usual with official monopolies, they often bred strong, if sub rosa, competition. Both these situations, whatever the prevailing atmosphere, permitted printed literature and learning to spread rapidly in Europe between the 16th and 20th centuries, and authorship and publishing flourished. The English Copyright Act of 1709 freed the individual author and enterprising publisher from monopolistic printers and recognized the right of both to negotiate for the best royalties and other terms for the publication of literary property. But this right had been recognized as early as Roman times, when publishers of the empire bid competitively for the exclusive privilege (for which they paid fees, not royalties) of duplicating literary creations. What was significantly new about the English act was its recognition of the right of the public to literary property after a specified term. That is the substance of modern publishing copyright; it protects authors in their rights to literary property and publishers in their acquisition of such rights; but more than that, it gives the public freer access to literary property after a limited number of years—under Queen Anne's act the term was 14 years, with the author retaining the privilege of renewing for another 14 years; in the United States it has come to be for 28 years, with the same privilege for another 28 years; in most other countries the term is the remaining years of the author's life plus 20 to 50 years.

The development of copyright practice since the early 18th century is an authentic clue to the growth of professional authorship and commercial publishing, and by the protection of copyright it was a stimulus to both. The limitation in the copyright period, in turn, is an authentic clue to the thirst for learning among the increasingly literate populace. Roman usage and common law had acknowledged the author's right—if he could assert it—to his property in perpetuity. English and later continental statutes freed this property for public use after protecting the author and publisher for specified periods of time. (See also COPYRIGHT.)

Toward Contemporary Publishing Practice.—Just as the monasteries gradually yielded their monopoly of publishing to the universities, and the universities to the corporations and guilds, and the guilds to the competitive printers, so the printers, under the pressure of this growing market for literary works, gradually

surrendered their dominant position to the booksellers.

None of these transitions took place in a day. Even as early as the 1580s in England the pressure of costs for printing equipment and the like forced printer-publishers to appeal to booksellers for capital and credit. Thus in 1582 Christopher Barker complained to the queen:

The booksellers being growen the greater and wealthier number have nowe many of the best Copies and keepe no printing howse, neither beare any charge of letter, or other furniture but onlie paye for workmanship . . . [with] the artifice printer growing every daye more and more unable to provide letter and other furniture, requisite for any good worke; or to gyve mayntenance to any such learned Correctours as are behovefull. . . .

Yet it was not until the 18th century that the bookseller had his great day as publisher. By then the reading public, especially in England, was growing much faster, and trade in popular new books (as distinct from the earlier staples of the whole industry: Bibles, commentaries, textbooks, dictionaries, and the like) was booming. To meet the new demands circulating libraries were established as early as the 1720s, and new authors were developing sufficiently large popular followings to be able to dispense with their former aristocratic patrons. By the late 18th century booksellers whose names continue to adorn publishing houses—such as Constable and Longmans—had already become kingpins of the publishing industry. Only a few decades later in the New World, Harper, Scribner's, Dutton, and Little, Brown had become well known.

Thus, with the rise of the bookseller contemporary publishing began, and with the rise of the novel and the novelist it flourished, especially in England and the United States. Both developments, reflecting the ascendancy of the middle classes, followed more deliberately on the continent, where literacy was slower to become nationwide and where extremes of wealth and poverty kept the middle-class markets small.

The unity of bookselling and publishing, in turn, persisted far longer in England than in the United States, where the great development of new writers (after piracy of English titles was successfully abated late in the 19th century) gradually stimulated the creation of independent publishing houses which were neither printers nor booksellers. This change brought with it new independent printers, binders, and booksellers: the first two produced, under contract, books arranged for by the new publishers, the third sold those books to the growing public. (See also BOOKSELLING.)

By the 1920s still newer publishers appeared in numbers (in England and the United States and in Germany and France on the continent) who were devoted almost exclusively to so-called trade books—that is, books of fiction, popular biography, history, memoirs, inspirational psychology, and books of sentiment and sentimental learning. Many houses among the older group and some among the newer continued to have special departments for Bibles, other religious books, school and college textbooks, medical books, and similar works that once were the foundation of the entire publishing industry. But the newer vogue was the trade publisher as such. The age of specialization had indeed set in, nowhere more strongly than in the United States, where the industry was less encrusted with old traditions and thus afforded the most suitable soil for the new flowerings.

Subscription Books.—One of the widest and most extensively developed methods of distributing books is by subscription: sales are assured by canvassing and pledging subscribers. Today reference works of all kinds—encyclopaedias, sets of children's books, some dictionaries, collections of popular novels—are distributed almost solely by this method.

Sales by subscription, it is believed, began in the 15th century when William Caxton (*q.v.*) is said to have initiated the method to finance the publication of *The Myrrour of the World*. It differed from the traditional practice, of having one sponsor or patron for the book, by enlisting the interest and money of many.

The idea proved attractive to printers and authors, but it was not until the turn of the 17th century that this form of distribution flourished. In most instances the issue remained a single volume, and the cost of production was assured by the persons who prom-

ised to buy the book. The method fell into disrepute when some printers, after selling a book in advance of publication, produced trash or no book at all.

In the 18th century larger sets of books were distributed by subscription. *Encyclopædia Britannica* in 1768 was one of the first. In some instances, where the cost of the initial production was excessive, prepublication offers were made, and subsequent sales were continued under installment or, as known in Great Britain, the hire-purchase plan. Mark Twain in the United States adopted this idea for the distribution of Gen. Ulysses S. Grant's *Memoirs*. In his monumental biography of Twain, Albert Bigelow Paine says that Twain was able to present to General Grant the largest single royalty check (\$20,000) ever given to an author up to that time, and before the volumes actually were published.

The Age of Specialization.—In the 20th century the number of new titles published each year has grown steadily, except for dips in war years or their immediate aftermaths. In 1963 about 19,000 new titles were published in the United States and over 20,000 in Great Britain. The relative size of the industry in the 20th century can be judged by comparing even its smallest annual volume of titles with that of earlier centuries. In the first half of the 18th century in England, for example, it has been calculated that the average annual number of new titles was about 93. The first quarter of the 19th century saw a jump to an average annual total of about 600. The annual growth of 20th-century totals makes it clear why specialization in publishing could so readily be supported and, indeed, why specialization had to come.

Within trade publishing itself the 20th century saw the development of hard-cover reprinters, paper-cover reprinters, specialized Western-story and detective-story publishers, science-fiction publishers, and others who profited greatly by concentrating on books for special, but sufficiently large, markets. In distribution, moreover, the old-fashioned bookseller—even the one who came to specialize in trade books—was supplemented by book clubs, other types of mail-order houses, and ordinary newsstands. While most regular trade publishers still printed editions ranging from 3,000 to 10,000 copies for most of their titles, for book clubs and paper-cover reprinters editions often ran to more than 100,000 copies and not infrequently to more than 200,000 copies. Clearly the old middle-class market had become a mass market by mid-20th century.

Beginning in the 1950s in the United States a new departure was the publishing of paper-covered books in editions ranging from 5,000 to 25,000 copies at prices that were a mere fraction of those for hard-cover books. These included reprints of great works of scholarship, science, religion, literature, and art. Many had long been out of print; often they had been issued originally by university presses or other specialized publishers with total sales of less than 2,000 copies. The great market for the new editions was found among college students and professors. So successful were these editions that many publishers began reprinting their serious books in paper-cover editions of their own. Some even issued new learned titles in this form for the student market. Specialized reprinters and even publishers of mass editions of detective stories and the like began to seek original manuscripts of a scholarly nature. In the main, however, the book clubs and others selling in mass markets continued to look to the regular publishers for titles to reprint.

To discover manuscripts for the regular publishing industry, two new occupations became prominent after the first quarter of the 20th century. The first was that of the manuscript scout, who often worked for publishers for a fee ranging from 1 to 2% of the retail price of books he might bring in. The second was that of the literary agent, who worked for authors and handled all their business relations with publishers for compensation in the form of 10% of the author's royalties and other income from his literary production. The growth of the agency business reflected further specialization in the publishing industry, whereby the publisher, becoming more a business manager, passed over his editorial functions to others. It also reflected the broadening market for authors, especially authors of fiction. To the magazine and newspaper serial rights were added motion-picture rights, dramatization

rights, radio rights, television rights, digest rights, and a series of others, the sale of which required complicated negotiations and contracts that most authors were incompetent to handle.

In facilitating distribution of books, further specialized agencies appeared in many countries. Advertising agencies sometimes added books to all the other products for which they sought to stimulate demand; others concentrated on books alone. In Germany and England, typically, about 5% of a publisher's net return was spent for advertising and promotion; in the United States the percentage was likely to be twice as high for books of average sales. For books with great sales possibilities much more was often set aside. Spending this money most effectively required skill and experience which the publisher often did not have; thus the advertising agency became involved.

Though trade books and paper-covered reprints grew in popular demand in the 20th century, growth elsewhere also added measurably to the flow of books. So great was the sale of school and college textbooks in the United States in the early 1960s that the securities of textbook publishers enjoyed an unprecedented boom in the stock exchanges. Especially notable too in the United States was the growth of the federal government as publisher—a development that reflected not only the rapidly increasing number of government studies but also the growth of federal services to those not ordinarily reached by regular publishers and regular means of book distribution. Far smaller in volume was the production of the university presses. Their work was largely in books of importance to science and learning which would, without these presses, probably have gone unpublished and thus unknown.

In the 20th century, motion pictures, radio, television, automobiles, massive illustrated magazines, and other vehicles of entertainment and enlightenment competed with the traditional book; but the book publishing industry itself enjoyed the most remarkable growth in its long and troubled history.

PUCCINI, GIACOMO ANTONIO DOMENICO MICHELE SECONDO MARIA (1858-1924), the greatest Italian opera composer of his period. Born at Lucca on Dec. 22, 1858, he represented the fifth (and last) generation of a musical dynasty which dated from the first half of the 18th century. Four of his ancestors held the post of *maestro di cappella* at the Cathedral of S. Martino at Lucca. It was intended that he should follow the family tradition, and he accordingly studied at the Istituto musicale Pacini (now Istituto musicale Luigi Boccherini); but a performance of *Aida*, which he saw at Pisa in 1876, revealed to him that his true vocation was opera. In the autumn of 1880 he entered the Milan Conservatory, where he remained for three years. His principal teachers there were Antonio Bazzini, a composer of symphonic overtures, and Amilcare Ponchielli, the composer of *La Gioconda*. In the summer of 1883 he graduated with an instrumental work, *Capriccio sinfonico*, the success of which attracted the attention of influential musical circles of Milan.

In the same year he entered *Le villi* in a competition for one-act operas. Though it failed to win a prize it was produced with great success in Milan in 1884, and was held to be remarkable for its dramatic power, its operatic melody, and, under the influence of Wagner, the important role played by the orchestra. The publisher Giulio Ricordi at once acquired the work and commissioned him to write another: thus began Puccini's lifelong association with

the house of Ricordi, whose head was to become a staunch paternal friend and counselor. While at work on the commissioned opera *Edgar*, based on a verse-drama by Alfred de Musset, Puccini set up home with Elvira Gemignani, the wife of a Luccese grocer. In 1886 she bore him a son, Antonio; in 1904, after the death of her first husband, her union with Puccini was legalized.

Edgar (Milan, 1889) was a failure; but with *Manon Lescaut* (Turin, 1893), based, like Massenet's *Manon*, on the celebrated 18th-century novel by A. F. Prevost, he achieved his first international success. In 1891 during the composition of *Manon Lescaut* he settled at the simple fishing village of Torre del Lago on the Lake of Massaciuccoli, remaining there until, three years before his death, he moved to Viareggio. *Manon Lescaut* was followed by Puccini's three most popular operas, which established him as the most remarkable Italian opera composer since Verdi. These were *La Bohème* (Turin, 1896), based on the autobiographical novel *Scènes de la vie de Bohème* by Henri Murger;

BY COURTESY OF THE ITALIAN INSTITUTE OF CULTURE, LONDON

GIACOMO PUCCINI

Tosca (Rome, 1900), after Victorien Sardou's five-act drama of that name; and *Madama Butterfly* (first version, Milan, February 1904; second version, Brescia, May 1904), after David Belasco's one-act play. In all three operas the librettists were Luigi Illica and Giuseppe Giacosa, who complemented each other in their work and were also the composer's best collaborators. With *La Fanciulla del West* (*The Girl of the Golden West*; New York City, 1910), also after a Belasco play, Puccini temporarily abandoned his lyrical style for technical experiments in harmony and orchestration under the influence of Debussy and Strauss. His single attempt at operetta, *La Rondine* (Monte Carlo, 1917), was unsuccessful. Then came *Il Trittico* ("Triptych") (New York City, 1918), consisting of three strongly contrasted one-act episodes: the sombre, horrific *Il tabarro*, after Didier Gold's *La Houppelande* (*The Cloak*); the sentimental tragedy *Suor Angelica*, on a libretto by G. Forzano; and the comedy *Gianni Schicchi*, also on a libretto by Forzano derived from Dante's *Inferno*. Puccini's last opera—some consider it his greatest—was *Turandot* (Milan, 1926), based on a play, *Turandotte*, by Carlo Gozzi. He died, before its completion, on Nov. 29, 1924, at Brussels. The last two scenes of the opera were completed from Puccini's sketches by Franco Alfano.

Puccini's approach to dramatic composition is expressed in his own words: "The basis of an opera is its subject and its treatment." The fashioning of a story into a moving drama for the stage claimed his attention in the first place, and he devoted to this part of his work as much labour as to the musical composition itself. The action of his operas is uncomplicated and self-evident, so that the spectator, even if he does not understand the words, readily comprehends what takes place on the stage. The majority of his operas illustrate a theme defined in *Il tabarro*: "Chi ha vissuto per amore, per amore si morì" ("He who has lived for love, has died for love"). This theme is played out in the fate of his heroines—women who are devoted body and soul to their lovers, are tormented by feelings of guilt, and are punished by the infliction of pain until in the end they are destroyed. In his treatment of this theme Puccini combines compassion and pity for his heroines with a strong streak of sadism: hence the strong emotional appeal but also the restricted scope of the Puccinian type of opera.

The main feature of Puccini's musico-dramatic style is his ability to identify himself with his subject: each opera has its distinctive atmosphere. With an unfailing instinct for balanced dramatic structure, Puccini knew that an opera is not all action, movement, and conflict; it must also contain moments of repose, contemplation, and lyricism. For such moments he invented an original type of

melody, passionate and radiant yet marked by an underlying morbidity; examples are the "farewell" and "death" arias that also reflect the persistent melancholy from which he suffered in his personal life.

Puccini's conception of diatonic melody is rooted in the tradition of 19th-century Italian opera, but his harmonic and orchestral style show that he was aware of contemporary developments, notably the work of the Impressionists and of Stravinsky. Though he allowed the orchestra a more active role, he upheld the traditional vocal style of Italian opera, in which the singers carry the burden of the music. In many ways a typical *fin-de-siècle* artist, Puccini nevertheless can be ranked as the greatest exponent of operatic realism.

PUDOVKIN, VSEVOLOD ILLARIONOVICH (1893–1953), Soviet film director, one of the greatest of the era of silent films, was born at Penza, Russia, on Feb. 21, 1893. Wounded and imprisoned for three years in World War I, he returned to the study of chemistry but was attracted to the theatre. D. W. Griffith's film *Intolerance* moved him to apply for admission to the State Institute of Cinematography in Moscow. He worked with Lev Kuleshov in certain early film experiments, directed an educational feature (*Mechanics of the Brain*) and collaborated on a comedy, *Chess Fever*. Pudovkin's best-known theatrical films are *The End of St. Petersburg* (1927), *Storm Over Asia* (1928), and *Mother* (1926), based on Maksim Gorki's novel. He was also occasionally an actor. His sound films included *Deserter* (1933), *General Suvorov* (1941), and *Admiral Nakhimov* (1948). Pudovkin died on June 30, 1953.

In two books, *Film Technique* and *Film Acting*, written for Russian film classes and first published outside Russia in 1929, Pudovkin explained his principles of scenario, directing, acting, and editing. His early films emphasize individuals within the Revolution somewhat more than did Sergei Eisenstein's (*q.v.*), but Pudovkin shared his great contemporary's liking for elaborate crosscutting of images (montage) to represent complex ideas.

(R. D. MACC.)

PUDSEY, a municipal borough (1899) of the West Riding of Yorkshire, Eng., lies between Bradford (4 mi. [6 km.]) and Leeds (6 mi. [10 km.]). Pop. (1961) 34,851. The trade of the town is varied, with woolen textile factories, tanning mills, foundries, crane-making, and light engineering works, together with other light industries. John Tunnicliffe, Herbert Sutcliffe, and Sir Leonard Hutton, eminent cricketers from the borough, played for Yorkshire and England. Pudsey has been in existence since before Saxon times and resisted Roman and Norman invaders and conquests. Fulneck, in the south of the borough, was chosen in 1743 as a Moravian settlement (now with a church and two schools). Farsley and Calverley were added in 1937. All three parts of the borough (Pudsey, Farsley, and Calverley) are mentioned in Domesday Book.

(W. R. C.)

PUEBLA, an interior plateau state of Mexico. Pop. (1960) 1,973,837; area, 13,096 sq.mi. (33,919 sq.km.), with its capital at Puebla. On the southeast corner of the Anáhuac Plateau, Puebla varies in elevation (5,000–8,000 ft.), with numerous fertile valleys formed by the Sierra Madre Oriental which runs through the state. Endowed with a temperate, semihumid climate, crossed by main highways running southward from the national capital, and traversed by rail and air lines, Puebla is one of the most densely populated states of Mexico.

Its strategic location and natural endowments in pre-Hispanic times are attested by innumerable archaeological sites and by its many towns and villages, notably Cholula (*q.v.*), Atlixco, and Tehuacán, a noted health resort. Coffee, sugarcane, fibres, maize, and cereals are its main crops. Onyx, gold, and other metals occur in its richly veined mountains. Numerous short, fast rivers provide hydroelectric power.

Its Nahuatl-speaking native peoples were highly developed at the coming of the Spaniards in the 16th century, and the latter founded many estates in this region, a main focus of their religious

and economic activities. In the 19th and 20th centuries Puebla developed as an agricultural-industrial area in the important corridor between Mexico City and its main seaport at Veracruz.

(Hd. C.; J. A. Cw.)

PUEBLA (PUEBLA DE ZARAGOZA), city of Mexico and capital of the state of the same name. Pop. (1960) 289,049. The centre of an important agricultural and industrial region of central Mexico, Puebla is 80 mi. (129 km.) N of the federal capital and from viceregal days has been considered the military key to the nation. The city was founded as Puebla de los Angeles by the Spaniards in 1532. According to church chronicles, the site was chosen as the result of a dream by Fray Julian Garcés who saw two angels with a line and rod pacing a beautiful plain flanked by tall volcanoes. Puebla is on a broad, healthful plain 7,050 ft. (2,149 m.) above sea level in the foothills of the Sierra Madre Oriental within view of Mexico's three highest snow-topped volcanoes, Citlaltépetl, Popocatepetl, and Ixtacihuatl.

Puebla is characteristically Spanish with noteworthy architecture similar to that of Toledo, Spain's great fortress city. The sumptuous cathedral, whose interior is rich with onyx, marble, and gold, was made a bishopric in 1550 and an archbishopric in 1903. Overshadowing the cathedral is the all-gold-leaf chapel of the Rosary in the church of Santo Domingo. The Casa del Alféñique, the "almond-cake house" (now a museum), was built in the 17th century of polychrome blue, white, and red tiles with white decorations and black ironwork balconies. The Teatro Principal (1790) was one of the first permanent theatres in the hemisphere. Puebla is the seat of a university, founded 1537.

A conservative, strongly Catholic city, Puebla was often considered politically reactionary in the history of Mexico. U.S. forces under Gen. Winfield Scott occupied the city (1847) during the Mexican War. Most famous of the battles fought in Puebla was the repulse of the French on May 5, 1862. In honour of its defender, Puebla was officially renamed Puebla de Zaragoza after Gen. Ignacio Zaragoza. The French again besieged the city, May 17, 1863, and captured it. Gen. Porfirio Díaz took the city April 2, 1867, and ended the imperialist occupation.

As an industrial centre, Puebla is known for its onyx working, Talavera tiles, cotton and woolen textiles, glass, soap, pottery, leather goods, and other light articles. (H. R. Hv.)

PUEBLO, a city of Colorado, U.S., situated on the Arkansas river at the mouth of Fountain creek, 120 mi. (193 km.) S.E. of Denver, at an elevation of 4,685 ft. (1,428 m.), the seat of Pueblo county. Pop. (1960) city 91,181; standard metropolitan statistical area (Pueblo county) 118,707 (for comparative population figures see table in COLORADO: *Population*). Pueblo lies near the great coal fields of the state, and is an important manufacturing, retail and trucking centre. At Minnequa, on the mesa south of the city, is one of the largest steel plants in the U.S. The irrigated region of 50,000 ac. (20,200 ha.) adjacent to Pueblo produces large quantities of red clover, onion, squash and cantaloupe seed as well as a major portion of the cucumber seed grown in the U.S. The Pueblo ordnance depot of the U.S. army (established in 1942) is on a mesa 14 mi. (23 km.) E. of the city. The Colorado state fair (established in 1886 and provided for by the state legislature since 1907) is held annually in August. The Colorado State hospital (psychiatric) is in Pueblo. Pueblo Junior college, a public school opened in 1933, became Southern Colorado State college in 1963 and was authorized to grant bachelor's degrees.

The site of Pueblo was visited by Lieut. Zebulon Montgomery Pike, who erected a temporary log breastwork on Nov. 24, 1806. In 1823 John McKnight established a trading post, which was soon wiped out by Comanches. From 1843 to 1854 there was a small settlement of mountain men as well as an adobe fort which was destroyed by Utes. A party of gold seekers located there in 1858. Gen. W. J. Palmer's Denver and Rio Grande railroad reached Pueblo in 1872 and he organized the Central Colorado Improvement company with the purpose of creating an industrial city. Reorganized in 1882 and again in 1892, it became the Colorado Fuel and Iron company and fulfilled the original purpose.

In June 1921 a sudden flood of the Arkansas river struck Pueblo, causing severe property damage and about 200 deaths. A \$4,000,-

000 flood-control system was immediately built, which effectively prevented any recurrence of the disaster.

The city established a council-manager form of government in 1950. (Hv. L. C.)

PUEBLO INDIANS, those groups of Southwestern U.S. Indians who live in pueblos (Sp. *pueblo*, "village" or "town"), compact permanent settlements, and who are characterized by intensive agriculture, distinctive arts and crafts (notably pottery and weaving), and complex religion. Up to the time of European arrival, however, they had no metals, and, like other North American Indians, no livestock (the only domestic animals being dogs and turkeys) and no wheeled vehicles. Native crops were corn, squash, beans, and cotton.

History.—The ancestors of the Pueblo Indians occupied the Southwest, as hunters and food-gatherers originally, thousands of years ago. (See INDIAN, NORTH AMERICAN: *Culture Provinces: The Southwest*.) Cultural advances, with introduction of new traits, primarily from Mexico, formed the developed Pueblo culture during, roughly, the 1st millennium of the Christian era. By the 16th century, when the first Spanish explorers opened the historic period in the Southwest, additional cultural changes had brought the Pueblos to a relatively high level of "Neolithic" culture, with agriculture, architecture, arts, and crafts. By that time, however, large portions of the formerly settled region had been abandoned—especially following the severe drought period in the 13th century—and the area occupied by the Pueblos was broadly similar to the modern distribution. Permanent Spanish occupation of New Mexico, which then included northern Arizona and the Hopi pueblos, began in August 1598. It was interrupted by the successful Pueblo Rebellion of August 1680, and Spanish political control and Catholic missionary effort were not reestablished until the 1690s in the New Mexico pueblos (the Rio Grande area, Acoma, and Zuñi); they were never reestablished among the Hopi. Except among the Hopi (and non-Pueblo, nonsedentary groups such as the Apache, Navaho, and others), the 18th century was a period of quietly firm and successful Spanish control of the Pueblo peoples. (See also NEW MEXICO: *History*.)

The Pueblo Peoples.—The modern and historic Pueblo Indians of New Mexico and Arizona include specifically: (1) the Hopi (or Moqui, as the Spanish called them) of northeastern Arizona, including the Tewa village known as Hano on First Mesa (founded about 1700 by refugees from the Rio Grande after the Pueblo Rebellion period); (2) the Zuñi in westernmost New Mexico, since about 1700 in one large town, before the Pueblo Rebellion occupying six pueblos in the same vicinity; (3) the seven Keresan-speaking pueblos of northwest-central New Mexico—the famous pueblo of Acoma the westernmost, then Laguna (long believed to have been established only in the 1690s after the Pueblo Rebellion but now known to have existed previously as a small village without a mission), and five just above the confluence of the Jemez Creek and the Rio Grande, on both streams (Zia, Santa Ana, San Felipe, Santo Domingo, Cochiti); (4) Jemez, just north and west of the Rio Grande, and formerly the Pecos (abandoned in 1838), speaking the same dialect; (5) the five Tewa villages north of Santa Fe—Tesuque, Nambe, San Ildefonso, Santa Clara, and San Juan; (6) the four pueblos which speak Tiwa dialects—Sandia and Isleta south of the Keresans and near Albuquerque, and Picuris and Taos north of the Tewa. Formerly there were other Tiwa pueblos and the related Piros south and east of Isleta.

The Jemez, Tewa, and Tiwa dialects are closely related, forming the Tanoan language family. Tanoan, Zuñi, and Hopi are all distantly related to each other and to languages of western North America in the Azteco-Tanoan stock (including Shoshone-Comanche, Ute-Paiute, Pima-Papago, and various Mexican tongues). Keresan, however, is not known to be related to any other language—in other words, the Keresans have been separated from any linguistic relatives for so long that no connections are recognizable.

Culture.—The distinctive Pueblo culture can be traced from relatively primitive seminomads of several thousand years ago

BY COURTESY OF THE MUSEUM OF NEW MEXICO

SAN ILDEFONSO PLAZA

Mexico.

Modern Pueblo social life centres around the village (which is also the political unit) though the pueblos are essentially theocracies. The western pueblos are organized as matrilineal clans and lineages, and households are based on matrilocal (uxorilocal) residence. Secret societies, each owned or controlled by a particular clan, perform calendric rituals for rain and tribal welfare. A tribal-wide *katchina* (*kachina*) cult is concerned with ancestors, and men's societies are responsible for protection and fertility ritual. In the Rio Grande region there is a dual village division into so-called Summer and Winter people, alternately responsible for pueblo activities; secret societies there deal primarily with curing rituals, and the *katchina* cult is less developed than it is in the other pueblos.

Native arts and crafts survive primarily among the Hopi,

where weaving and basketry are still (1960s) practised and where the Hopi-Tewa revived pottery making in the 1890s. But the most remarkable pottery revival took place at San Ildefonso, where Maria Martinez developed the famous blackware now made by several Tewa pueblos. Silver and turquoise jewelry is currently produced in most pueblos, but silver working is not aboriginal.

Modern Pueblo Indians have retained the pre-Spanish way of life to a surprising degree. They have added to their material inventory, since 1600, such items as livestock, metal tools, new crops (e.g., wheat, peaches, chili peppers from Mexico), European and, later, modern U.S. clothing, automobiles and radios; after World War II, television aerials appeared on many of the picturesque little adobe houses in the Rio Grande Valley. These changes necessarily have affected ideas, attitudes, and general outlook. But even in the Rio Grande pueblos close to Santa Fe

who subsisted on wild plants and animals, and who had comparatively few and simple implements of flaked stone, bone, wood, and other plant materials. More advanced traits (mostly from Mexico) developed with appearance of cultivated or semidomesticated corn (maize; *Zea mays*) in southwestern New Mexico more than 4,000 years ago; pottery, first dated in that area to about 2,000 years ago; beans and pumpkins; pithouses (from a northerly source?); polished stone (e.g., ax blades) and, later, stonemasonry and permanent surface structures; cultivation of cotton; domestication of turkeys; the bow and arrow; the hard cradleboard; and many others.

At least a few important religious concepts came from the south—notably the horned or plumed serpent. Basic polytheistic theory, colourful ritual, masked prayer dances, altars and offerings, derived from the south or—perhaps more likely—from the same original matrix as the more complex religion of native

PUEBLOS AND LINGUISTIC AREAS OF THE PUEBLO INDIANS

and Albuquerque the basic fabric of Pueblo social system, community of organization, and native religion, with modifications only of detail, has fully and successfully survived the blows of drought and arroyo-cutting in the 1200s, incursions and attacks by non-sedentary Indians, Spanish domination after 1600, three and one-half centuries of Christian missionary efforts, and (at least into the 1960s) the impact of modern technology.

PUERPERAL FEVER (CHILDBED FEVER), a term implying infection of some part of the female reproductive organs following childbirth or abortion. The equivocal term "puerperal pyrexia" covers all cases of fever of 38° C (100.4° F) and over occurring during the first ten days following delivery or miscarriage, but due to either genital or extragenital lesions. Such cases are notifiable to the civil authority in most civilized countries and the notifying physician should clarify the diagnosis later, if possible. Puerperal infection is most commonly of the raw surface of the interior of the uterus after separation of the placenta (afterbirth); but pathogenic organisms may also affect lacerations of any part of the genital tract. By whatever portal, they can invade the blood- and lymph-stream to cause septicemia (blood poisoning), cellulitis (inflammation of cellular tissue), and pelvic or generalized peritonitis (inflammation of the abdominal lining). The severity of the illness depends on the virulence of the infecting organism, the resistance of the invaded tissues, and the general health of the patient.

Illegal abortions performed in unhygienic surroundings commonly result in puerperal fever.

History.—The disease was accurately described in the writings of Hippocrates (5th century B.C.): "If a woman in childbed have erysipelas of the womb she will usually die"—and this held true until 1935 (see below). William Harvey was the first to describe (1651) the placental site as "one vast ulcer" in women with childbed fever. Charles White of Manchester identified (1773) puerperal with "surgical" fever, then and later the scourge of hospitals; advised postural drainage of the womb in the lying-in period and, by his insistence on cleanliness in the conduct of deliveries and on isolation of infected patients, made a famous advance in the art of midwifery. Alexander Gordon declared (1795) that puerperal fever was a contagion seizing only such women as were attended by a doctor or midwife in contact with other infected patients. Jean Louis Baudelocque remarked (1789) the greater incidence of fever when hands or instruments had been introduced into the birth canal. I. P. Semmelweis (*q.v.*) rediscovered these facts and demonstrated (1847) that infection was rife among women delivered by doctors and students who dissected cadavers and far less common among women attended only by midwives. He earned tragic unpopularity by advocating washing of the hands in antiseptic solution before attendance on women in labour. Meanwhile in the United States the poet-physician Oliver Wendell Holmes (*q.v.*) had published *The Contagiousness of Puerperal Fever* (1843) and was similarly abused; however, by 1855, when the essay was reprinted with additional evidence, his views had begun to prevail.

Causative Organisms.—"Humours" and "miasmata" were thought to be the causative agents of all fevers until, in 1879, Louis Pasteur isolated a dotlike microorganism, grouped in short chains, from the discharges of a woman with fatal puerperal fever. This, the hemolytic streptococcus, remains the most deadly of all killers. In 1935 Rebecca Lancefield (U.S.) and Ronald Hare (England) identified a single group of these streptococci as the cause of severe puerperal fever, tonsillitis, scarlet fever, and fulminating surgical infections; and Leonard Colebrook showed that these organisms are not normally present in the human

vagina but are conveyed mediately to puerperal patients from the upper respiratory tract of their attendants or contacts.

Other common organisms producing this infection are the staphylococci (casual inhabitants of the skin, of pimples, carbuncles and many other pustular eruptions); the anaerobic streptococci, which flourish in devitalized tissues such as may be present after long and injurious labour and unskilled instrumental delivery; *Escherichia coli* and *Clostridium welchii* (inhabitants of the lower bowel); and, rarely and fatally, the bacillus of tetanus.

Signs and Symptoms.—Fever, sometimes with rigors, usually begins on the third day postpartum; the pulse rate quickens and general prostration develops, as with any acute infection of the body; the uterus remains enlarged and tender, the discharges from it being profuse or scanty, or purulent or malodorous. Danger signs are persistent high fever, repeated rigors, rapid pulse rate, insomnia, diarrhea, and delirium. In favourable cases the infection remains localized to the genital tract or pelvis and recovery is the rule, even without specific medication. Pelvic peritonitis or cellulitis will prolong the illness and may require surgical drainage; invasion of the bloodstream or general peritoneum is of the utmost gravity and in the 1960s accounted for about half of all deaths during the lying-in period. The most serious residue of the illness in all its forms for those who recover is sterility.

Prevention.—The conduct of labour, delivery, and the recovery period must meet the high standards of asepsis and antiseptics essential to modern surgery. It remains true that the more natural the labour and the less the interference, the lower the incidence of sepsis. Conversely, the longer or more traumatic the labour, the higher the morbidity. Accurate antenatal care, prognosis, provision for likely difficulty, skilled attendance, minimizing of fatigue or loss of blood, rigid asepsis and antiseptics, and the greatest gentleness in all maneuvers can prevent the development of very nearly all infections. It is imperative that persons harbouring possibly harmful organisms, especially in the upper respiratory tract, be excluded from attendance at the childbed, and that any such infection in the mother be effectively treated. The antenatal period is devoted to improving the general health of the pregnant woman and detecting and treating any disease.

Curative Treatment.—When symptoms of puerperal fever appear, the patient must be isolated; the nature of the infecting organism determined by culture of swabs from the genital tract, and all contacts examined and made to undergo bacteriological investigation, both to detect the source of the infection and to prevent its spread. While awaiting the results of this, the patient herself and any puerperal contacts should commence a course of sulfonamides or a wide-spectrum antibiotic. The stricken woman is nursed in a semi-upright position to ensure free drainage of discharge, and given blood transfusion if anemia is present.

Until 1935 the treatment of such patients was purely supportive and was successful only if the low invasive power of the infecting organism or the patient's own resistance prevented the development of generalized disease. If septicemia or general peritonitis appeared the morbidity rate was very high indeed. With peritonitis due to the hemolytic streptococcus, recovery was the rare exception. In 1935 the sulfonamides were first used clinically at Queen Charlotte's Isolation Hospital, London, by Colebrook and Meave Kenny, as specific antidotes for severe hemolytic streptococcal infections. Later, pneumococci, gonococci, and *E. coli* yielded to this chemotherapy: there was an immediate and worldwide drop both in the mortality rate of puerperal fever and in its apparent incidence, since the pyrexia could be controlled below notifiable limits within a few hours. Then, in the 1940s, from Alexander Fleming, Howard Florey, and co-workers in England, came penicillin, with its power to check staphylococci as well.

With the discovery of more and more antibiotic drugs, almost every organism associated with puerperal fever has been defeated; severe illness or death from this cause is almost unknown in civilized countries. The mere occurrence of a case was, by the 1960s, an embarrassment to an obstetric unit, for it told of a breakdown in preventive measures which had come to be valued

far above cure. Puerperal and neonatal morbidity, when it did occur, was most commonly caused by strains of staphylococci, resistant to various antibiotics, which had become resident in hospitals and among the population. They caused inflammation of the breasts; and eye and skin infections in the newborn. The purely prophylactic use of antibiotics in hospital or their indiscriminate administration in general practice increased this danger of the appearance of resistant strains of organisms. Therefore, the tendency was to limit the haphazard use of these drugs, to choose their type more carefully, and to prefer the sulfonamides when these were equally effective.

PUERTO BARRIOS, the principal port of Guatemala, served chiefly by cargo and passenger ships of the United Fruit Company. Pop. (1964) 32,071 (mun.). Named for Justo Rufino Barrios, president of Guatemala from 1873 to 1885, it was constructed as the Caribbean terminus of the railway, built by foreign contractors from the coast to Guatemala City, which realized a century-old Guatemalan dream of a national commercial outlet through a deep-water Atlantic port. The government became dissatisfied with control of the facilities by foreign interests, however, and constructed a competing port at Santo Tomás (1955) and a highway paralleling the railroad. Puerto Barrios is also connected with the capital by air. (W. J. G.)

PUERTO CABELLO is a city and port of Venezuela in the state of Carabobo. Pop. (1961) 52,222. The mean average temperature of the port is 80° F (26.6° C). Puerto Cabello has a well-protected harbour accessible to the largest vessels calling at Venezuelan ports, with docks, warehouses, a navy yard and dry-dock facilities. The city is connected with Valencia, the capital of the state, by a highway and railway over a 2,000-ft. (610-m.) pass and is considered a natural outlet for the agriculturally rich and commercially important Valencia basin. Commerce dominates the economy of the city, but there are small processing industries. Ten miles from the city, on the Pan-American highway, is a modern petroleum-chemical plant erected by the government. Puerto Cabello was sacked by pirates many times during the colonial period and was a favoured smuggling centre for the Dutch, operating from Curaçao. The city suffered much damage in the Wars of Independence. Simón Bolívar was defeated there in June 1812. Subsequently the port changed hands several times. José Antonio Páez, national hero and long-time president of the republic, led the attack which forced the final Spanish surrender at Puerto Cabello in 1823. The story goes that the waters of the harbour are so smooth that a single hair (*cabello* in Spanish) could moor a vessel to the dock, hence the name Puerto Cabello. (J. J. J.)

PUERTO DE SANTA MARÍA, EL, a seaport of southwestern Spain in the province of Cádiz, region of Andalusia, is situated at the mouth of the Guadalete River in the Bay of Cádiz, 9 mi. (15 km.) SW of Jerez de la Frontera by rail (10½ mi. [17 km.] by road). Pop. (1960) 35,505 (mun.). It is an attractive town with many buildings of architectural interest. It competes with Jerez in the production and blending of sherry wines, which are exported. It once housed naval arsenals and shipyards and was an oceanic captaincy general. From it Alonso de Ojeda sailed to the West Indies. (M. B. F.)

PUERTO LA CRUZ, lying in northeastern Venezuela on the Caribbean, is one of the country's outstanding petroleum-handling ports. Pop. (1961) 59,099. It is the petroleum metropolis and the shipping terminal for the large output of the Greater Oficina oil-producing area and for smaller oil fields of the state of Anzoátegui. Important oil pipelines from these fields as well as from small ones in the neighbouring states of Guárico and Monagas focus upon Puerto La Cruz. The port is also the site of very large oil storage facilities and of refineries. It is connected with Barcelona, just 6 mi. distant, by railway. (L. W. E.)

PUERTOLLANO, a town of south-central Spain, province of Ciudad Real, lies in the valley of the Ojailén River, 22 mi. (36 km.) SSW of Ciudad Real by road. Pop. (1960) 53,136 (mun.). The valley was an important sheep-farming area in the Middle Ages, the pastures of the Order of Calatrava being particularly famous. The town has three sections: the medieval town; the 16th-century area, built when the woolen industry was flourishing; and the newest part, dating from the discovery of coalfields in 1873 and stretching along both banks of the river for 2 mi. (3 km.). By 1918 there were 25 mines, but the industry then suffered a depression; by 1953 production had risen again and Puertollano became an important industrial centre. Industries include distilleries for bituminous shale and the manufacture of nitrogenous fertilizers. The town is linked by rail with Ciudad Real and Badajoz. (M. B. F.)

PUERTO MONTT, city and port of southern Chile, capital of scenic Llanquihue province, occupies a narrow plain between Reloncaví Sound and large morainal hills to the north. It is a popular lake district resort, adjacent Tenglo Island and the superb volcano-dominated scenery being major attractions. Pop. (1960) 41,681. The city's strategic position between Chile's core area and the islands to the south makes it an important communications centre. It is a terminus for the state railway, serves as home port for state-owned and other shipping, and offers air service to the north and south and to Argentina. There are naval and air stations, an important lumber industry, and small-boat yards. The city, named for Manuel Montt (*q.v.*), was founded in 1853 by a group of German immigrants. (J. T.)

PUERTO PLATA, a province in northern Dominican Republic. Area 726 sq.mi. (1,880 sq.km.). Pop. (1960) 163,896. Its southern boundary is the Cordillera Septentrional (to 3,993 ft. [1,217 m.]), which is the nation's leading coffee region. Puerto Plata is also one of the leading producers of corn (maize), bananas and tobacco and a significant dairying region. The province was established in 1875. Its capital, San Felipe de Puerto Plata (called Puerto Plata), pop. (1960) 19,073, was founded in 1503 by Columbus. It is the nation's second port and an industrial centre. Thirty miles to the west are the ruins of Isabela (reputed to be the first European town set up in the new world), founded by Columbus in 1493. (D. R. D.)

PUERTO RICO (COMMONWEALTH OF PUERTO RICO, ESTADO LIBRE ASOCIADO DE PUERTO RICO), an island and an autonomous commonwealth voluntarily associated with the United States. It is the smallest and the most easterly of the Greater Antilles, the major island group of the West Indies (*q.v.*), which form the broken northern boundary between the Caribbean sea and the Atlantic ocean. To the west and just out of sight beyond the 70-mi. (113-km.) Mona passage lies the island of Hispaniola. To the east lie the Virgin Islands, one of which, St. Thomas, can be seen on a clear day from the eastern shore. New York, the main U.S. port of departure for Puerto Rico, lies more than 1,500 mi. (2,400 km.) N.W. Directly south, across about 600 mi. (960 km.) of Caribbean sea, is the coast of Venezuela. Puerto Rico is nearly rectangular with a length from east to west of 113 mi. (182 km.) and a width of 41 mi. (66 km.). Its area is 3,349 sq.mi. (8,674 sq.km.) or 3,435 sq.mi. (8,897 sq.km.) including adjacent islands. This article is divided into the following sections:

I. PHYSICAL GEOGRAPHY

1. Geology and Physiography.—Puerto Rico and the other Greater Antilles are formed by the high parts of a 1,300-mi. (2,100-km.) chain of mountains whose base and bulk are buried beneath the sea. These mountaintop islands are the oldest of all the land masses in the West Indies. In contrast, the Lesser Antilles, which form the eastern boundary of the Caribbean sea, are of more recent formation, and volcanic activity is sometimes still apparent there. Near Puerto Rico the land mass offers its greatest relief contrast in height and depth. To the north of Puerto Rico, running more or less parallel to the island, exists the deep valley in the Atlantic floor known as the Puerto Rico Trench (formerly called the Brownson Deep). The deepest part of this trough lies about 75 mi. (121 km.) to the northwest of Puerto Rico; there the floor of the Atlantic goes down 27,498 ft. (8,381 m.). To the south too the land falls off sharply below sea level. About 55 mi. (89 km.) S.W. of Puerto Rico the Caribbean reaches a depth of more than 17,000 ft. (5,200 m.). If the base of this chain of mountains were elevated to sea level, it would become one of the most imposing land masses in the world. Indeed, the highest point in Puerto Rico, Cerro de Punta, 4,389 ft. (1,338 m.), would attain an altitude greater than that of Mt. Everest.

The island's central mountain chain, the Cordillera Central, rises almost directly out of the sea on the west coast of the island and extends eastward, finally terminating in the Sierra de Luquillo in the northeast and in the Sierra de Cayey in the southeast. While this rugged terrain covers about 70% of the island's area, the fertile coastal plains extend like a fringe between the mountains and the Atlantic on the north and the Caribbean on the south. Geologists agree that while Puerto Rico cannot be considered a volcanic island, in the sense that some of the Lesser Antilles might be so classified, the land mass was formed by early volcanic activity during the upper Cretaceous. In general terms, the Cordillera Central is underlain by lavas and volcanically derived sediments resulting from this igneous activity. In the west a large body of serpentine occurs, and in the central and southeastern areas bodies of coarser plutonic rocks, quartz, diorites and granodiorites are found.

The coastal plain on the south side of the island is not so wide nor so naturally fertile as the northern coastal plain. The north-south drainage divide runs parallel to the Caribbean coast about 10 mi. (16 km.) from the shore line. As would be expected, thus, the southern side of the central mountain chain presents a more precipitous drop to the sea than that found on the north. To the north, most of the principal rivers, such as the Río Grande de Loiza, Río de la Plata or Río Grande de Arecibo, descend to the Atlantic through foothills and slowly declining slopes. The flood plains formed by these rivers are extremely fertile.

2. Climate.—While Puerto Rico lies just within the tropics, its climate is usually agreeable. The average annual temperature is about 76° F. (about 24° C.) and there is no sunshine, on aver-

age, for only five days a year. On the coast the winter average is 75° F.; for the summer months it is 80°. In the interior at an altitude of 1,500 ft. the average winter temperature is 70°; during the summer it is 75°. The absolute minimum temperature recorded in Puerto Rico was 39° at an altitude of 3,000 ft. Frost may occur at higher altitudes but has never been officially recorded. The maximum recorded temperature in San Juan is 94°. Cool, invigorating sea breezes, constantly brought by the trade winds which bathe the islands of the West Indies, help to soften the effect of the hot sun. During the summer months these winds come directly from the east or slightly southeast. During the winter they shift and come from the northeast. At night, gentle land breezes coming down from the mountainous interior bring cool and refreshing air to the coastal areas, causing a drop of 6° or 7° from the day temperature.

The trade winds also bring abundant rainfall, which for the island averages 74.4 in. (1,890 mm.) annually. It rarely rains for more than a few hours at a time, even during the rainy season, which lasts from May to November. The coastal areas are cooled in the late morning or afternoon by light showers during the warmer months of the year. The variation in rainfall recorded in different parts of the island is much greater than the temperature variation. The rain forest of Sierra de Luquillo, the northeastern branch of the central mountain chain, which receives the trade winds first, recorded an average annual rainfall of 184 in. over a ten-year period. In the southwest corner of Puerto Rico annual rainfall drops to about 30 in. The island is subject to occasional tropical storms. The winds, which reach a velocity of 150–200 m.p.h., are usually accompanied by torrential rains. The storms, which rarely last more than a day, occur from July to October.

3. Vegetation.—The erosive effect of a heavy rainfall on the precipitous slopes of the central mountain range of the island is counteracted by a particularly tenacious soil bound together by clinging and abundant vegetation. The wide variation of rainfall, a fairly rich soil and different altitudes produce a great variety of plant life. Because of the extensive cultivation of the land, the vegetation in a relatively natural state is limited to the insular and national forest reserves located at higher altitudes in the western, central and eastern sections of the island. The tropical rain forest of the Luquillo National Forest reserve, located at the eastern end of the island, is composed of a great variety of trees, clinging and hanging vines and a thick undergrowth of shrubs, ferns and thickets. The junglelike density is almost impenetrable without the aid of a machete, a sharp, long, broad-bladed knife. In this area wild orchids can be found. Trees include bamboo, palm, cedar, ebony, calabash, whitewood, lancewood, boxwood and logwood.

Along the coastal plains, which probably were covered once with a thick forest growth, sugar cane and pineapples are grown. In the northwest corner of the island and in the mountain areas tropical fruits of all varieties are produced. In the western highlands, together with the coffee bush, can be found a great variety of citrus fruits. In addition to the common fruits such as bananas and oranges the island produces papayas, pomegranates, avocados, guavas and mangoes. Spices such as ginger, pepper, vanilla and chicory are also grown.

4. Animal Life.—Physically isolated at an early geological age and densely populated, Puerto Rico has very little wild animal life. Bats, birds, a scarce and harmless species of snake and several varieties of harmless lizards, together with the mongoose and rat, comprise Puerto Rican wildlife. For the patient bird watcher the island offers a wide variety of species of birds, nesting or in transit. About 190 species have been identified, and of these 89 are known to nest. About 36 birds are endemic to Puerto Rico. Thrushes, tanagers, bullfinches, flycatchers, warblers, plovers, terns and sandpipers are the birds most commonly seen.

The waters around the island are excellent for sport fishing. Yellow-fin tuna, white marlin, sailfish, dolphins, kingfish and wahoo are only a few of the commoner varieties which can be found 2 to 5 mi. from the coast. There are fine black bass in the fresh-water reservoirs of the island.

II. GEOGRAPHICAL REGIONS

Puerto Rico may be divided into three geographical regions, using as the principal criteria the contrasting altitudes.

1. Lowlands and Coastal Plains.—Geographers have calculated that 27% of the island's land can be classified as flat or

PHYSICAL FEATURES AND MAJOR CITIES OF PUERTO RICO

gently rolling lowlands. With one or two minor exceptions offered by small inland valleys, one near Caguas and the other near Cayey, this region is comprised primarily of land along the coastal fringe of the island. Depending upon the availability of water, the flat or rolling coastal lands are the most fertile areas of Puerto Rico. The abundant rainfall on the north coast assures production, but on the south coast, particularly in the southwest corner in the Lajas valley sector, the flat rolling land needs irrigation. In the Lajas valley the insular government built an extensive irrigation project which collects in artificial lakes the heavy rain that falls on the nearby highlands, brings the water down over hydroelectric dams and channels the distribution into the arid valley.

For the most part the coastal plains produce the bulk of the island's sugar crop. About 30 sugar mills, or *centrales*, located in this region produce more than 90% of the island's sugar. More than 20% of this sugar is produced on the north coast and about 30% is produced on the irrigated plains of the south coast. Some coastal land lacking in rainfall or fertility is used as pasture. Prior to the completion of the irrigation project, the Lajas valley was used primarily in this way. On the north coast about 35 mi. W. of San Juan, near the port of Arecibo, pineapple production has been expanding. The coastal area has some unproductive land in mangrove swamps and in limited areas where sand dunes have moved inland. By far the best of the island's beaches can be found on the sheltered west coast. The north coast also has excellent beaches wherever offshore reefs serve to break the heavy Atlantic surf. The Luquillo beach east of San Juan is perhaps the most popular and widely known.

2. Highlands.—In contrast to the coastal plains is the markedly mountainous terrain of the central part of the island, which accounts for about 36% of the land area. This extensive area is marked by high local relief with little flat land. Most of the slopes range from 30% to over 60% grade. This region, comprised of the Cordillera Central, the Sierra de Cayey and the Sierra de Luquillo, includes the highest peaks of the island drainage divide.

Heavy rainfall and fertile soil permit extensive cultivation of this region in spite of the sharp slopes. Coffee is the main crop in the area which extends from near the west coast to the centre of the island. The shrub which produces the coffee bean is very sensitive to temperature variations and grows best in shaded areas between 1,000-ft. and 3,000-ft. altitude; orange and grapefruit trees and the broad-leaf banana plants are utilized for shade. As a result of the cultivation of coffee in the western mountain area, the impression is given of a cleared, well-gardened forest. Two insular forest reserves, Maricao and Toro Negro, with picnic facilities and lookout towers, can be found in the western and central mountain areas.

The eastern mountainous section, with the exception of the Sierra de Luquillo, receives less rain than the western highlands do, and the vegetation is less thick and the land unprotected by a covering forest. Tobacco is the principal commercial crop. Small

farms produce subsistence crops, and extensive pasture areas can be found. The Sierra de Luquillo, where the tropical rain forest is located, has a recreation park with trails, swimming pools and lookout towers.

3. Rolling Hill Land.—The area of the island which lies between the two extremes of the flat coastal plains and the markedly mountain terrain can be described as rolling hill land; it comprises the remaining 37% of the land surface. Foothills adjacent to the central core of mountains are included in this area. In this region the unique limestone belts of the northeastern and north central section of Puerto Rico are found. This area, which is similar to the cockpit area of Jamaica (*q.v.*), is of a more recent geological age than the rest of the island, having been formed during the Tertiary period. The limestone plateau, at one time under the sea, once lifted and exposed to rain and wind erosion, was slowly converted into striking karst topography. The area is characterized by precipitous cliffs, caves and large caverns, deep depressions or sinkholes and undissolved limestone remnants or *mogotes*, which resemble conical haystacks. In this area rivers such as the Tanamá or Camuy disappear suddenly and, running underground, appear just as unexpectedly miles away. In spite of the rugged terrain, the irregular valleys among the *mogotes* and precipices are cultivated with some success by the small farmer. Subsistence crops, vegetables and fruit are the main products.

4. Mona, Culebra and Vieques Islands.—These small islands are politically and culturally linked to Puerto Rico. Fifty miles southwest of the western port of Mayaguez is Mona Island (*q.v.*), consisting of a limestone plateau of about 20 sq.mi. Light rainfall and infertile soil make Mona an island of poor vegetation and no permanent inhabitants. Culebra Island (*q.v.*), half the size of Mona, is situated halfway between Fajardo, the east coast port of Puerto Rico, and the port of Charlotte Amalie in St. Thomas, Virgin Islands. Culebra's population of 887 lives mostly in a small town located in the excellent harbour of Puerto Grande. Vieques Island has an area of 57 sq.mi. and is located 10 mi. S.E. of Puerto Rico. While most of the island is used for naval installations by the U.S. government, the small population has struggled to maintain itself by cultivating the sparse soil.

III. THE PEOPLE

1. Racial Characteristics.—Puerto Ricans are mostly descendants of a European stock, specifically Spanish, with an admixture of Negro and some Indian (mainly Arawak or Boriquén) strains. The dominant Spaniards absorbed or eliminated the Indians within a short time after the conquest of Puerto Rico, but physical characteristics of the aboriginal Indian are still evident in dental formation, colour and texture of hair and facial structure, particularly of the people in the mountainous interior.

Negroes were introduced early in the 16th century as slave substitutes for the disappearing Indians. However, under the lenient Spanish treatment many of the slaves earned or were granted freedom. Partly as a result of this attitude the slave population was always smaller than that of free coloured people. In 1846, when Puerto Rico's slave population reached the top figure of 51,265, the number of free Negroes was 175,791 and the combined slave and free coloured population was slightly more than 50% of the total population. As Puerto Rico's population increased during the 19th century, with the slave trade effectively halted and slavery abolished, the percentage of Negroes in the over-all population declined rapidly until by the 1960s less than 20% of the population was classified as nonwhite. However, to be socially considered white, it is not necessary to meet the strict biological requirements of having only white ancestors.

The *jibaro* is the small isolated independent farmer who has struggled for centuries to sustain himself in the rugged Cordillera Central. Within recent years the *jibaro* has been converted into an insular cultural, if not political, symbol.

2. Language.—Puerto Rico draws upon a rich Spanish cultural heritage. The Spanish language is spoken everywhere and is used throughout the school system. English is taught as a secondary language, and in the urban areas and particularly in the commercial establishments, English is commonly heard. Rare would

be the businessman who could not carry on a limited conversation in English, and many are fluent bilinguals.

3. Religion.—For the almost 400 years of Spanish control over Puerto Rico the Roman Catholic Church occupied an exclusive place as the state-protected religion. Indeed, Puerto Ricans came to look upon the crown and the church as one. Almost every town on the island has, in true Spanish style, a Catholic church located on one side of the central plaza.

After the change of sovereignty in 1898, evangelical sects became active on the island. Most of their followers are drawn from the lower classes and the expanding urban middle class. Approximately 20% of the population is considered to be active in one or another of the evangelical groups. The cost of the insular evangelical work has been sustained by the various missionary boards in the United States, but the local churches have been encouraged to become economically independent.

A growing number of islanders are believers in some form of spiritualism. These people come from all classes of society but are said to be found most commonly among groups undergoing marked social change.

4. Customs and Culture.—Spanish influence is waning in the social customs of the people of the large towns and cities. The growing industrialization and increasing U.S. influence are converting Puerto Ricans from a two-class, stable, patriarchal, agrarian society to a mobile, three-class, modern, industrial society in which women are achieving a place of equality with men. The rising rate of divorce is an indication of these changing social conditions. Among adolescents of the large cities the chaperon is a thing of the past. Still, in some of the small towns of the interior on Saturday evenings or holidays, the custom of strolling around the plaza, boys in one direction and girls in the other, can be observed. Birthdays, weddings and deaths are occasions for social gatherings. Wakes, *rosarios* (nightly ceremonies in commemoration of a death) and *rogativas* (group supplications) are still observed in rural areas.

In music the fused influence of the African and Latin strains is most notable. Both popular and traditional music have a distinct local flavour. The island has actively cultivated an interest in classical music, and several symphonic groups function, one with the financial backing of the government. A chief contributor to this cultural renaissance was the cellist Pablo Casals.

The island government, concerned at the apparent lack of concerted efforts to preserve the historical and cultural heritage of the island, organized the Institute of Puerto Rican Culture, which, with local branches in all the leading towns, undertook to encourage, through scholarships and prizes, the expression of local artists, musicians and writers. Museums were established, traveling exhibitions were sponsored, drama groups were encouraged, and a series of scholarly publications was initiated, all with the purpose of making Puerto Ricans appreciate their cultural roots.

IV. HISTORY

The first inhabitants of Puerto Rico, originally from the Amazon basin of South America, reached the island by means of the archipelago of the Lesser Antilles about 600 years before the arrival of the Spaniards. These Arawak Indians, living in small villages, were organized in clans and led by a cacique or chief. They were a peaceful people who, with a limited knowledge of agriculture, lived on a variety of domesticated tropical crops such as pineapples, manioc and batatas supplemented by shellfish and other sea food. Anthropologists estimate their numbers to have been between 20,000 and 50,000. On an island naturally fertile, the Arawaks lived an easy life disturbed only by occasional visits from their cannibal Carib neighbours on the islands to the south and east. At the time of discovery, Carib Indians occupied most of the Lesser Antilles, the Virgin Islands and Vieques Island.

In 1493 Christopher Columbus, at the peak of his popularity, left Spain on his second voyage to the Indies with an elaborate expedition of 17 ships and about 1,500 men. At the island of Guadeloupe, the Spaniards rescued several Arawak Indians who had been taken from Boriquén, the Indian name for Puerto Rico, by the Caribs. Columbus agreed to return them to their island,

and on Nov. 19, 1493, the expedition anchored in a bay on the west coast of Puerto Rico. Columbus formally took possession of the island in the name of Ferdinand and Isabella, the rulers of Spain, and named it San Juan Bautista. Two days were spent on the island before the ships moved westward to Hispaniola, where the first settlement in the new world was established.

A. SPANISH RULE

1. Early Settlement.—For 15 years the island was neglected except for an occasional visit by a ship putting in for supplies. In 1508 Juan Ponce de León (*q.v.*), who previously had accompanied Columbus, was granted permission to explore San Juan Bautista in recognition of his valuable colonizing efforts in eastern Hispaniola. On the north coast, Ponce de León found a well-protected bay which could offer safe harbour for a large number of sailing vessels. The harbour was named Puerto Rico because of its obvious excellent potentialities. In this area was located the most important settlement on the island; through time and common use the port became known as San Juan while the name Puerto Rico came to be applied to the whole island.

The peaceful and friendly relations with the Arawak did not last long. The Spaniards expected the Indians to acknowledge the sovereignty of the king of Spain by payment of gold tribute. The Indians were to be instructed in Christian ways. In return for this education, which was rarely given, the Arawaks were expected to work and supply either more gold or provisions of food. In 1511 the Indians rebelled against the Spanish, who with their superior arms rapidly subjugated them.

Placer mining of gold was continued by Indians brought from other islands and by Negroes introduced from Africa by some of the early traders. After the 1530s, however, gold production markedly declined, and the Spanish colonists, with slave labour, turned to agriculture. By 1550, with financial aid from Spain, several small sugar mills were in operation on the island.

Puerto Rico did not prosper economically, however. Carib Indians from neighbouring islands made frequent raids, carrying off food and slaves and destroying property. The colony continued to lead a precarious existence, ravaged by plagues and plundered by French, British and Dutch pirates. Repeatedly during the mid-16th century the French burned and sacked San Germán, the second community to be established on the island. Under such adverse conditions people began to leave the island whenever opportunity offered.

In the second half of the 16th century Spain, recognizing the strategic importance of Puerto Rico, undertook to convert San Juan into a military outpost. The fortress El Morro, built with the financial subsidy from the Mexican mines, was well constructed and perfectly located to dominate the narrow entrance to the harbour. Later, a stronger and larger fortress was built to the east and on the Atlantic side of the city. In the early 17th century the city was surrounded by a stone wall, 25 ft. high and 18 ft. thick, two parts of which still stand. These defenses made San Juan almost impregnable.

Sir Francis Drake attacked the town in 1595 but failed to gain the harbour. Three years later George Clifford, 3rd earl of Cumberland, had complete military success but was forced to abandon his conquest owing to an outbreak of plague among his troops. In 1625 a Dutchman, Bowdoin Hendrik, burgomaster of Edam, boldly sailed into the harbour, captured and burned the town, but failed to subdue El Morro.

San Juan, as the most exposed military outpost guarding the heart of Spain's new world empire, received political and economic attention from the mother country. However, the rural inhabitants of the interior of the island were ignored by Spain and scorned by the presidial residents of San Juan. As the French, English, Danish and Dutch fought over and settled the Lesser Antilles during the 17th and 18th centuries, rural Puerto Ricans, ignoring the edicts of Spain, found profit in clandestine trade. Ginger, hides, sugar, tobacco and cattle from the island were in great demand, and while the colonial authorities of San Juan rarely ventured out of their walled defenses for fear of the reprisals of the buccaneers the rural settlers prospered in a modest way through

contacts with the non-Spanish European traders. No large plantations were established, and the farmer, with little help, cultivated his own land. Contrary to the fears of Spain, this contact with foreigners did not corrupt the islanders, who remained loyal and were willing to participate in aggressive expeditions.

2. Liberal Reforms.—In 1797 the British Gen. Sir Ralph Abercromby, who had captured Trinidad, unsuccessfully attacked Puerto Rico. The British considered the island—a centre of clandestine trade and of operations for quasi-piratical expeditions, and a refuge for runaway slaves—a weak link in the chain of defense of the Spanish empire. The failure of Abercromby was due in part to the important economic and administrative changes in the Spanish colonial empire which were carried out in the latter half of the 18th century by representatives of the Bourbon rulers of Spain. In the case of Puerto Rico it was hoped that the island might become an economic asset rather than a financial drain on the Spanish crown. Trade relations between the island and Spain were liberalized, agricultural production was stimulated, the island as a whole was integrated into the system of military defense, and, above all, concerted efforts were made to break down the social dichotomy which had developed between the walled city of San Juan and the interior.

The liberal reforms of the enlightened despotism of the Spanish Bourbons coincided with and encouraged rapid population growth, introduction of new products and the beginning of commercial agriculture. Population was estimated in 1765 at 45,000; in 1775 at 70,250; in 1787 at 103,051; and in 1800 at 155,426. By the end of the 18th century there were 34 towns on the island. Immigrants from the Canary Islands, French settlers from Louisiana or Haiti and Spaniards from Santo Domingo, which had been turned over to Napoleon, accounted in part for the increase in population. These newcomers brought with them new ideas and methods of producing marketable crops. Coffee, introduced into the island in 1736, became an important export item by 1776. Sugar production, which had always been small, was undertaken on a large scale by augmented slave labour. From 1765 to 1800 the slave population increased from 5,037 to 13,333.

When Napoleon invaded Spain and placed his brother, Joseph Bonaparte, on the Spanish throne (1808), the colonies of South and Central America asserted their right to govern themselves in the name of the imprisoned Bourbon king, Ferdinand VII. This claim to temporary self-rule eventually evolved into a revolutionary movement for independence. In Puerto Rico, however, for various reasons, the sequence of events and their results were different. The communities of the interior of Puerto Rico, with one exception, offered little objection to the strict rules of Spain's mercantilist policy, which for many decades had ceased to have effect on them. Most of the residents of San Juan, on the other hand, dependent upon administrative and military positions, were most willing to follow the orders of the central government of Spain acting in the absence of the king. Puerto Rico, which had asserted its loyalty by repelling the English, undertook to recapture Santo Domingo from the French.

As the revolutions progressed on the southern and central mainland, loyal Spaniards reluctant to leave the colonies found refuge in Puerto Rico, which was being used as a supply depot for military movements on the continent. In recognition of its loyalty and in a belated move to liberalize an outmoded colonial system, the Spanish government granted Puerto Rico in 1815 ample economic liberties. The island was opened to all non-Spanish Catholics, the ports were permitted to trade with non-Spanish countries, and free land was granted to the new settlers.

3. Economic and Political Development.—By the end of the 19th century the population had increased to nearly 1,000,000, and the value of foreign trade had increased considerably from an estimated \$1,000,000 in the 1820s to \$30,000,000 annually. During the 1800s imports from the United States rarely dropped below 20% of the total goods received; exports to the U.S. fluctuated between 50% and 15% depending in part upon U.S. tariff restrictions. By 1899 the United States was buying 61% of Puerto Rican sugar production. The area devoted to sugar had been slowly expanding, and the processing was becoming more cen-

tralized. Coffee, in the late 19th century, provided the principal source of income for the island; its production quadrupled between 1862 and 1898.

Political development in Puerto Rico during the 19th century was characterized by periods of liberal advance counteracted by long periods of conservative reaction. In part, this was due to the changes occurring in the Spanish government, and in part due to the antiquated Spanish colonial administrative policy.

During the first half of the 19th century, two short periods of relative political freedom were enjoyed. From 1809 to 1814 and from 1820 to 1823 Puerto Rico was declared an integral part of Spain with the right to elect representatives to the Spanish *Cortes*, or parliament. Ramón Power y Giralt, an able liberal, was selected during the first period and succeeded in revoking the absolute powers of the island's colonial governor. In the latter period Demetrio O'Daly secured the separation of the military authority from the colonial administrator. Freedom of the press was also permitted. On each occasion moderate colonial rule was thwarted by the return of royal absolutism in Spain.

In 1837, when a fairly permanent constitutional monarchy was established in Spain, Puerto Rico failed to benefit because it was argued that the colonies were not true Spanish provinces and therefore should be governed by special laws. For more than 30 years Puerto Rico waited for special legislation to ease the despotic rule of military colonial governors. During this waiting period, political thought in the island began to crystallize. A liberal current of opinion, remembering the success of previous periods, requested assimilation into the Spanish government and permission to be represented in and governed by the *Cortes*. A bloc of conservative opinion strongly approved of the status quo. A small third group advocated complete independence.

4. Movements Toward Self-Government and Independence.—A local commission was elected in 1865 to draw up a report on the basis of which a governmental reform might be carried out. The majority report, which declared that the abolition of slavery was the *sine qua non* of any political reform, provoked a shocked reaction among the island and peninsular conservatives. The alarmed colonial government took steps to curtail what was feared to be a growing movement of rebellion. Some of the more outspoken and respected islanders were ordered to be arrested and sent to Spain for trial. Thus provoked, a small group of radicals committed to independence attempted an uprising, for which, however, inadequate preparation was made. *El Grito de Lares*, the abortive revolt of Sept. 23, 1868, brought forth severe reprisals on all island liberals. However, the abdication of Queen Isabella II of Spain was forced by a republican government, which pardoned all the political prisoners. The first Spanish republic extended to Puerto Rico its third period of constitutional government, 1868–74, during which slavery was abolished.

During the 1880s a movement for political self-government under Spain led by Román Baldorioty de Castro replaced the sentiment in favour of integrating Puerto Rico into the Spanish government. Again a liberal political movement, this time autonomy, was denounced as disloyal and was violently suppressed in 1887, an infamous year in Puerto Rican history. Such treatment only served to solidify the movement for local self-government, and in 1897 the Partido Unionista (Autonomy party), now guided by Luis Muñoz-Rivera, through co-operation with the Liberal party in Spain, achieved its objective. The autonomous government granted was parliamentary in form but retained the governor general as a representative of the Spanish king. He was empowered to disband the insular parliament and suspend civil rights. The two-chamber parliament was empowered to legislate for the island, create and control an insular tariff and levy local taxes. Puerto Rico's representation in the Spanish *Cortes* was also increased. Any change in the governmental organization had to be first approved by the insular parliament.

5. Spanish-American War.—The Spanish-American War (*q.v.*) prevented the islanders from putting into effect the new government. In May 1898 Adm. W. T. Sampson bombarded San Juan for a short time without serious results. Facing token military resistance and with general popular acceptance, Gen. Nelson

A. Miles landed a U.S. force of about 3,500 men in July, and after a short campaign hostilities were ended on Aug. 12.

B. UNDER THE UNITED STATES

1. Early Years.—On Oct. 18, 1898, the island was turned over to the U.S. forces and Gen. John R. Brooke became military governor. Puerto Rico was ceded to the U.S. by the treaty signed in Paris, Dec. 10, 1898 (ratified by the U.S. senate Feb. 6, 1899). In the work of policing the country, in the accompanying tasks of sanitation, construction of highways and other public works, accounting for the expenditure of public funds and establishing a system of public education, the military control which lasted until May 1, 1900, proved effective in bridging the period of transfer from the control of Spain to the system under the United States civil government. The United States congress passed the Foraker act, under which civil government was instituted in May 1900. Under this act the U.S. element exercised the controlling power; this, however, having proved distasteful to many Puerto Ricans, the Organic law was subsequently amended to give a wider native participation in the government. The Olmsted act, approved by congress on July 15, 1909, placed the supervision of Puerto Rican affairs in the jurisdiction of an executive department to be designated by the president. The people, however, demanded a larger measure of local control. The majority also asked for U.S. citizenship and many other changes. As a result, congress passed a new Organic act (the Jones act), which came into effect on March 2, 1917. Under its terms Puerto Rico became a territory of the United States "organized but unincorporated," and citizenship of the United States was conferred collectively on Puerto Ricans, allowing the right to retain the old status if preferred. Only 288 persons declared in favour of the latter. The local civil government, however, even with modifications, fell far short of the measure of self-government which Puerto Ricans expected in light of the democratic tradition of the United States. Key officials, including the governor, were presidential appointees and thus beyond local control.

In spite of the legal limitations on political autonomy, a climate of freedom was slowly developed as a result of the change of sovereignty. At first this new order, being abrupt, new and imposed from above in some instances, was sometimes mistrusted, resented and misunderstood, but in the long run it was recognized as beneficial and assimilated by the islanders. For example, labourers were allowed to organize for collective bargaining and to affiliate with labour unions in the United States; the Anglo-Saxon legal procedure of assuming innocence until proved guilty brought slowly a feeling of security and freedom from political persecution; the separation of church from state, resulting in open competition for religious adherence, demonstrated the new climate in a practical way; government programs which dealt directly with the vital needs of the people for education, health and sanitation, regulation of working conditions and public facilities all reflected a change designed to remedy centuries of neglect.

2. Economic and Social Changes.—The economic reorientation of the island as a result of the change in sovereignty had almost an immediate and profound effect on all aspects of life. Included within the U.S. tariff walls, Puerto Rican agricultural products, particularly sugar, had a ready market. Aided by the adoption of U.S. currency and by unobstructed financial movement, Puerto Rico experienced within a short period a large capital investment which revolutionized the production of sugar. Sevenfold acreage expansion (1899 to 1939), new disease-resistant plants, rapid transportation facilities, large and efficient cane-grinding mills and complete corporate management within a generation converted the economy of the island into one in which 75% of the population directly or indirectly was dependent upon sugar. Land which had sustained small farmers producing crops and dairy products for local consumption was absorbed by the sugar corporations.

The island was forced to import its foodstuffs. Coffee was neglected at a time when weather conditions and transportation problems dictated financial and government aid. Only tobacco production experienced growth, which failed to be sustained after

the 1920s when United States smokers shifted from cigars to cigarettes.

The shock of these economic changes might have been absorbed in spite of the island's limited resources if at the same time Puerto Rico had not been undergoing a severe social change as a result of the application of modern sanitation means and medical knowledge to a people with a very high death rate. The population was threatening to double its number in two generations. The two counterpressures—expansion of corporate control over the limited productive land and increasing population pressure—reached an explosive stage at the time when the economic depression occupied the attention of government officials in the United States. Recurring hurricanes joined with declining exports to aggravate the economic distress of the island.

3. Political Development.—With one exception, political parties which had developed since the change in sovereignty had centred their attention on modifications in the political relations between the island and the U.S. federal government. The Republican party limited its program to a plea for statehood for the island. The Union party worked for greater autonomy. In the 1920s the Nationalist party rose to affirm the ideal of immediate independence. The one exception was the pro-U.S. Socialist party, led by the highly respected labour leader Santiago Iglesias. This party had expressed since its foundation a concern for the plight of the labouring classes of the island. Nevertheless, its effectiveness had been hampered by insufficient popular support, due primarily to the concentration of attention upon the issue of the political status of the island.

In the mid-1930s, with Pres. Franklin D. Roosevelt's New Deal policies radically enlarging the previously accepted concept of the function of government as that of maintaining order and protecting the citizens, Puerto Rico was not neglected. More important than the much-needed temporary relief were the steps taken by the Puerto Rican Reconstruction administration (P.R.R.A.), designed to readjust the distribution of economic power on the island. A restrictive quota was placed over sugar production. Legal procedures were initiated to enforce a long-neglected law limiting corporate holdings to 500 ac. Thus the process of increasing the sugar acreage was to be reversed and Puerto Ricans were to be returned to their small farms. A model sugar mill was to run on a co-operative basis to compete with the private mills. Coffee and tobacco growers were to receive long overdue attention.

This radical program provoked the open opposition of the sugar interests, locally vocal through the Republican party. The Socialists accepted the program in a tacit fashion. Their reluctance was due to the fact that the young radical wing of the heirs of the Autonomy party, led by Luis Muñoz Marín, the son of Luis Muñoz-Rivera, was recognized in Washington and on the island as the local political proponent of the economic reform.

The success of the New Deal measures was jeopardized by two unconnected factors. Unforeseen administrative and financial problems forced a curtailment of the objectives of the P.R.R.A. No longer was a complete readjustment of the island's economic structure possible; the P.R.R.A. took on a more temporary or experimental nature. The second factor was the interjection of the status issue on the political scene by the U.S. government in answer to Nationalist violence. Taking the form of a vindictive offer of independence under adverse economic conditions, the proposal served to realign again the political parties into pro- and anti-independence groups.

The incipient political movement for economic reform originally fostered by the New Deal and temporarily sidetracked was surprisingly successful in the election of 1940. This new political movement took the form of a political party, led by Muñoz Marín, called the Popular Democratic party. Organized to improve the conditions of the lower classes, particularly the hard-working *jibaro* of the mountainous interior, the new party's platform was summarized by the slogan "Bread, land and liberty." The island electorate had agreed that the political status was not in issue and that economic and social problems took precedence. Tenuous control over the island legislature and a new-style colonial governor, Rexford Guy Tugwell, allowed the Popular Democratic party to initiate such eco-

economic reforms as redistribution of land, enforcement of minimum wage and hour laws, an enforced progressive income tax law and the establishment of an economic development program. In recognition of partial fulfillment of its announced aims the Popular party was overwhelmingly backed by the island electorate in 1944. In 1946 Pres. Harry S. Truman named Jesús T. Piñero, a Puerto Rican, as governor, the first Puerto Rican to occupy that post. In 1947 the U.S. congress amended the Organic act of Puerto Rico to permit election of governors by popular vote. Muñoz Marín was elected Nov. 2, 1948, and took office in Jan. 1949. In spite of efforts at economic development, the post-World War II years were marked by large-scale emigration to the eastern United States, mainly New York city.

Governor Muñoz Marín and the Popular Democratic party turned to deal with the temporarily postponed problem of political status. The economic recovery experienced by Puerto Rico under the guidance of the *Populares*, rather than freeing the island from its economic ties to the United States, changed these relations from unrestrained exploitation by absentee sugar corporations to controlled industrial production which allowed the islanders to receive greater benefits from the original capital investment. Obviously any political change had to take into consideration these essential economic relations. The solution was found in the expansion of local political autonomy which did not affect adversely the economy of the island.

4. Establishment of the Commonwealth.—In 1950 the U.S. congress offered to Puerto Rico for its approval or rejection a series of changes in the law which governed the relationship between the federal government and Puerto Rico. These changes if accepted would eliminate all sections dealing with the creation of the local insular government and would turn over to the people of Puerto Rico the power to create their own government under a constitution of their own making. Under the guidance of Governor Muñoz Marín the islanders accepted the offer of congress and drew up a constitution. Duly approved by the people and the congress, Puerto Rico's constitution was proclaimed on July 25, 1952, and the Commonwealth of Puerto Rico came into being. (See *Administration and Social Conditions*, below.) After some years of operation the full measure of self-government is still being explored and defined. During this period, Puerto Rican extremists dramatized their desire for independence with an attempt to assassinate President Truman on Nov. 1, 1950, in Washington. They attracted world-wide attention on March 1, 1954, when several members of the Nationalist party shot and wounded five congressmen in the house of representatives in the U.S. capitol. Nevertheless, in the judgment of the general assembly of the United Nations, expressed in a resolution of Nov. 27, 1953, Puerto Rico is a self-governing political unit associated voluntarily with the United States and is no longer considered a colonial territory.

V. POPULATION

The population of Puerto Rico, 2,349,544 in 1960, had more than doubled since 1899, when it was 953,243. The 1950 census gave a population of 2,210,703; of whom about 40% were urban and 60% rural; 79.7% were classified as white and 20.2% as Negro. This small island, with a population density of over 700 per square mile, is one of the most densely populated areas of the world. One of the principal reasons for the growth was the application of modern medical knowledge to a previously underprivileged island, resulting in a radically declining death rate. From 1901 to 1960 the island's death rate dropped from 36.7 per 1,000 to a subnormal 6.7, a lower figure than that in the United States. The birth rate declined at a much slower rate: from 43.2 in 1947 to 31.5 in 1960. The difference (+24.8) between the birth and death rates in 1960 left a high rate of natural increase (a ratio of four births to every death on the average), thus accounting for the high population density. According to the demographers, by the mid-1960s the population of Puerto Rico should have reached an estimated 2,500,000 persons. The death rate should rise automatically to a more normal 12 per 1,000 as the age distribution approximates proportionately the same distribution attained in the United States. The birth rate can be expected to continue to de-

cline as the standard of living rises and the middle class increases.

One factor which allowed Puerto Rico to keep pace economically with the rapidly growing population was emigration to the United States. The difference between the numbers of those leaving and those returning to Puerto Rico in the 1950s resulted in a net exodus of about 50,000 a year. This figure was only slightly under the average yearly natural increase of 60,000 for the same period. For the most part, Puerto Ricans who went to the United States were young persons of working age with an occupation or skill. Those who returned to the island were older people, already past their productive years. However, in the early 1960s the emigration rate declined considerably and many people returned to the island from the U.S.

The metropolitan areas have absorbed much of the island's population growth. The rural inhabitants, particularly in the western highlands where the coffee haciendas are found, have been migrating to the cities on the north and south coasts. Some indication of this migration can be seen in the growth of San Juan (merged with Río Piedras), which in the 1950s doubled its population to well over 500,000 and which, including suburbs, had increased to about 650,000 by the mid-1960s.

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government.—The government of the Commonwealth of Puerto Rico was established by a constitution drawn up by representatives of the Puerto Rican people meeting in a convention; approved by the electorate of the island, March 3, 1952; and ratified by the congress of the United States. This constitution, proclaimed July 25, 1952, provides for an autonomous form of representative government and guarantees the liberties and rights of its citizens through a bill of rights. The people of Puerto Rico are free to modify the constitution as long as such modifications do not conflict with the U.S. constitution or the Puerto Rican Federal Relations act, which, as its title indicates, defines to a limited extent the relations between the commonwealth and the federal government. This act was adopted "in the nature of a compact" by the U.S. congress and the Puerto Rican people. To change this compact the consent of both groups would be required.

The constitution provides for a government whose powers are distributed among the executive, legislative and judicial branches. Franchise is restricted to citizens 21 years of age and over. The governor of Puerto Rico is elected by popular suffrage every four years, and unlimited re-election is permitted. He appoints, with the consent of the commonwealth senate, the heads of departments, who form, with other agency directors selected at the governor's discretion, his advisory council. Aside from the departments such as labour, education and justice, the commonwealth has a department of co-operatives.

The members of the legislative branch, composed of a senate and a house of representatives, are elected for four-year terms. There are eight senatorial (two members each) and 40 representative districts. Eleven senators and eleven representatives are chosen at large. The commonwealth constitution guarantees, by means of automatic appointment based on island-wide voting strength, the representation of minority parties in the legislature.

The island is divided into 76 municipalities, each of which has an elected mayor and assembly whose primary functions are to administer schools, health centres, poor relief and other services of the commonwealth.

The Puerto Rican electorate sends a resident commissioner to the U.S. congress for a term of four years, but he has no congressional vote. Puerto Ricans do not vote in the U.S. presidential elections, but emigrants on the mainland may do so subject to local electoral laws.

2. Taxation.—Since the citizens of Puerto Rico (after one year's residence on the island all U.S. citizens fall into this category) are not represented with a vote in the federal congress, they are not subject to federal taxes. The commonwealth government is sustained in part by the local revenue laws, which in general provide for taxes about one-quarter to one-third lower than those of the mainland. A graduated personal and business income tax, an excise tax and a property tax are the main sources of local revenue.

The excise tax, which has produced more than half of the commonwealth's locally collected revenue, was used to reduce spending on nonproductive luxury items, the purchase of which tended to drain off potential local capital.

3. Living Conditions.—The middle- and upper-class living conditions in Puerto Rico are comparable to those of the United States. The expected difference between rural and urban areas is marked, but the standard of living of the agricultural worker has improved. Federal and commonwealth minimum wage laws cover every important industry and areas of agricultural production. Strict enforcement and periodical revisions ensure a just compensation for the working class. The hourly wage received by labourers is considerably lower than that received by workers in similar industries in the United States, but private professional salaries for the growing middle class are generally on a par with salaries for similar occupations in the United States. Government workers such as teachers, clerks or administrators are not so well paid as private professional workers or federal government employees in the U.S.

The labour force of the island has remained for some time slightly over the 635,000 mark. Unemployment, which fluctuates seasonally, has rarely dropped below 15% of the labouring force.

Since more than half the goods and services which Puerto Rico consumes come from the United States, the general price level follows closely the level on the mainland. Local products are naturally less expensive than imported items, but inability to expand local farm production has caused prices of local goods to be increased at a much faster rate than that of imported goods prices. Large supermarkets, including four large consumer co-operatives, serve the San Juan, Ponce and Mayagüez metropolitan areas.

Faced with the increased migration from the mountains to the cities, particularly to the San Juan area, and a rapidly growing population, the commonwealth government working in close co-operation with the Federal Housing authority was able to undertake during the years after World War II extensive programs of construction of low-cost housing. Although the inadequately serviced housing areas were not eliminated completely, strict enforcement of government laws concerning zoning, new constructions and renovations, coupled with a methodically planned slum-clearing program, improved immeasurably the living conditions of the workers.

4. Welfare Services.—In the mid-1960s about 20% (in 1964, \$97,000,000) of the total budget of the commonwealth was spent on providing health and public welfare services for the people of the island.

Several hundred public health clinics, functioning under the supervision of doctors and nurses, offered preventive and curative medical services. Six general district hospitals, six tuberculosis hospitals and a large psychiatric hospital were run by the com-

BY COURTESY OF THE GOVERNMENT OF PUERTO RICO

LIBRARY, UNIVERSITY OF PUERTO RICO

monwealth. The health department offered assistance to the aged, needy families and the handicapped. Almost half of those attending public school received free lunches, milk depots were conducted to supply free milk to preschool-age children, and annually about 80,000 pairs of shoes were distributed free to needy students.

All workers, both industrial and agricultural, are completely covered in case of accidents by a compulsory state insurance fund, which has rendered excellent service for over a generation.

5. Justice.—The commonwealth constitution provides for a uniquely unified judicial system consisting of a general court of justice comprised of the supreme court and the court of the first instance. The latter is organized in two divisions, the superior court with 30 judges and the district court with 55 judges. The whole judicial system is administered by the chief justice of the supreme court and his office of court administration. This integrated system permits maximum flexibility. Jurisdiction and venue questions do not prevent a case from being considered. Appeals may be carried to the supreme court in Washington.

6. Education.—Compulsory education has been in effect since 1899. To keep pace with the growing population, the commonwealth assigned to education during the 1950s a larger percentage of its budget than did any other Latin-American country, 30%.

This percentage was generally maintained through the mid-1960s. Over 95% of the elementary school-age children are registered and attend classes; about 85% of those eligible attend the secondary schools, and about 50% of those eligible attend high schools. Teaching is in Spanish in the public school system, but special emphasis is given to the teaching of English as a second language. In the 1950s, partially as a result of a successful adult education program, the island illiteracy rate dropped from 24% to less than 15%, and the decline continued in the 1960s. Special English instruction for prospective migrant workers was provided.

The land-grant government-financed University of Puerto Rico, near San Juan, which includes a technical campus with a nuclear reactor in Mayagüez, has an international faculty and student body. The other island colleges include the Roman Catholic Sacred Heart college in Santurce and the Catholic University of Puerto Rico in Ponce, as well as Inter-American university at San Germán which is affiliated with the United Presbyterian Church.

VII. THE ECONOMY

The economy of Puerto Rico is closely tied to that of the United States. No trade barriers exist to prevent interchange of goods between the two areas. During the first half of the 20th century Puerto Rico's agrarian-based economy functioned primarily from the sale of sugar and its by-products. After 1956 the economy of the island shifted noticeably from one based on

agriculture to one based on manufacturing and industry.

1. Agriculture.—The production of sugar, dairy products, tobacco, coffee, fruits and vegetables annually accounted for about 15%-20% of the island's total net income. Sugar, processed by more than 30 cane-grinding mills, accounted for about 50% of the agricultural income. This production, subject to a federal quota of 1,125,000 tons annually, supplied about 10% of the sugar consumed in the United States. In recent years, due partly to adverse weather conditions, the island failed to fill its quota, and the island government extended limited aid to sugar growers. The government planned to stabilize the production of sugar at 1,268,000 tons produced on only 300,000 ac. of the most productive flat coastal land.

Coupled with this stabilization is the mechanization of the cane-cutting process. With increasing wages and rural emigration, large cane growers have turned to machine substitutes for human labour.

Livestock production, second only to that of sugar, contributed about 30% of the agricultural income. Accounting for more than half the livestock income was the sale of milk and its by-products. Eggs, beef, pork and poultry accounted for the remainder. With 400 dairies and 13 large pasteurizing plants, the commercial dairy industry was well developed, and it was the only phase of agricultural production which showed signs of growth.

Although coffee production declined in the 20th century until it scarcely satisfied local demands, the haciendas in the western mountain area are still numerous. Land dedicated to coffee produced anywhere from 150 to 200 lb. per acre, depending upon varying conditions. Some 35,000 ac. of tobacco, principally in the eastern central part of the island, brought an annual average return of about \$8,000,000 to the growers.

2. Industry.—The remarkable industrial development which occurred in Puerto Rico was due to the government's Economic Development program, particularly that phase known as Operation "Bootstrap," which by the mid-1960s had established 1,000 new factories on the island. These plants in large part explained why, after the mid-1950s, manufacturing and industrial production surpassed agriculture as a source of wealth. Stimulated by ten years of grace from taxes, availability of government-built factories for lease or purchase and ready access to the United States market, corporations did not hesitate to establish branch centres of production on the island. At first new industries were those which hoped to profit by low labour costs or were associated with agriculture. After 1956 textile mills, chemical and metal plants (i.e., industries which involved a higher capital investment) were established in growing numbers. The most important included oil refineries, fertilizer plants and chemical plants to develop petroleum by-products. On the south coast in Ponce there is a large cement factory, and in Santurce, near San Juan, there is an ironworks; both these industries have played an important part in the construction activity which accounts for 5% of the total net income of the island.

3. Power.—The electric power of the island is provided by a government agency, the Puerto Rico Water Resources authority, which came into existence in 1942. As a result of the government's program of rural electrification and a marked increase in industrial demand, the power production of the island by the late 1950s had increased to well over 1,000,000,000 kw.hr. annually. Industrial consumption of power increased 134% between 1942 and the late 1950s. By the mid-1960s total consumption had risen to more than 2,500,000,000 kw.hr. annually.

4. Trade.—Between 80% and 90% of the value of imports comes from the United States. Puerto Rico imports about 50% of its food, and 43% of consumers' expenditure is for food. Rice, lard, pork and dairy products are the most important imports. The island's expanding industrial climate has required the importation of capital equipment for productive uses, and raw or semi-processed goods for further elaboration and sale. About 40% of foreign imports are raw material, including crude oil from Venezuela and the Netherlands Antilles, to be refined and consumed or shipped to the United States.

All but about 5% of the value of Puerto Rican exports is sent to the United States. To the older exports of sugar, molasses and rum have been added electrical appliances, textiles, pharmaceuticals and plastic goods.

The deficit in the balance of trade is in part made up by payments and expenditures of the federal government on the island. About 90% of this is expenditures of the defense department and payments to veterans. Gross fixed domestic investment in Puerto Rico increased to more than \$485,000,000 in the mid-1960s. The island continued to develop and expand its profitable tourist business.

5. Banking and Currency.—Since Puerto Rico functions economically as an integral part of the United States, the currency of the island is the same as that of the U.S. The island's banking system is also integrated within the U.S. banking structure. A number of local banks, two Canadian banks and three United States banks operate under the close supervision of the insular government. Seven of the banks are members of the Federal Deposit Insurance corporation. The branches of the United States banks are indirectly related to the federal reserve system.

A legal maximum of insular indebtedness, placed at 10% of the aggregate tax valuation of property, has limited the financial operations of the government. Puerto Rico has never defaulted in the payment of principal or interest of the insular debt.

6. Transport and Communications.—The island has an extensive system of highways serving every community. In the mid-1960s there were more than 3,000 mi. of paved streets and highways and more than 250,000 motor vehicles. No railroads for public use exist on the island; during the cane-cutting season some sugar corporations operate local railroads to bring cane to the *centrales*.

Eleven ports of widely varying importance are open for handling freight and some passenger service. San Juan, Ponce and Mayagüez receive most of the cargo ships. First-class passengers are accepted in limited numbers on the freighters, but no passenger line links the island with the United States. A French line passenger service connects Puerto Rico with the European continent. Most of the Puerto Rican visitors and migrants travel by air. The San Juan International airport, equipped for jet passenger service, is connected with many of the major cities in the U.S. British, French, Dutch, Spanish and Latin-American airlines have frequently scheduled flight services connecting Puerto Rico with other points around the Caribbean and abroad.

The United States postal service offers complete service on the island. Three commercial cables extend from Puerto Rico to the mainland. There is a government and commercial wireless service. The island has about 30 commercial radio stations and 10 commercial television stations. The government operates an educational radio and television station. See also references under "Puerto Rico" in the Index.

(T. G. Ms.)

PUFENDORF, SAMUEL, BARON VON (1632–1694), German publicist and jurist, best known for his treatise on natural law and international law, *De jure naturae et gentium libri octo*, was born near Chemnitz, Saxony, on Jan. 8, 1632, the son of a Lutheran pastor. He commenced theological studies at Leipzig university but soon turned to jurisprudence and studied mathematics and natural law under Erhard Weigel at Jena. Leaving Jena in 1657, Pufendorf took service as a tutor in the household of the Swedish minister at Copenhagen. When Sweden declared war, the whole retinue was imprisoned. Pufendorf occupied his captivity of some eight months reflecting on what he had read in the works of Grotius and Hobbes and mentally constructing a system of universal law. On his release, he went to Leiden where he published in 1661 the fruits of his reflections in the work *Elementa Jurisprudentiae universalis*, in the plan and

structure of which his mathematical training is very evident.

Karl Ludwig, the elector palatine, to whom the work was dedicated, created a chair of the law of nature and nations for Pufendorf at Heidelberg, the first chair of its kind in the world. His next work was written under a pseudonym, Severinus de Monzambano: *De statu imperii germanici ad Laelium, dominum Trezolari, liber unus*. It took the form of a bitter attack, supposedly by a Veronese nobleman, on the constitution of the Holy Roman Empire and the house of Austria, and created a great sensation.

In 1670 Pufendorf left Heidelberg for the University of Lund, Swed., where he produced in 1672 his great work, the *De jure naturae et gentium libri octo*, and, in the following year, the *De officio hominis et civis* which is in the main a résumé of the *De jure naturae*.

Grotius had pointed out the dualism between a natural and a positive law of nations. Where Richard Zouche stressed the precedence of the latter, Pufendorf followed Hobbes in maintaining the priority of the natural law; he differed from Hobbes, however, in proclaiming that the natural state was one of peace, not of war, albeit a precarious peace unless given positive support. For, though originating from God in that God created men as social beings, natural law, for Pufendorf, is concerned with man in this life—as he is, with all his failings—and with external conduct, and it derives from human reason alone: man as a prospective citizen of heaven is the concern of moral theology. This search for natural law in the dictates of human reason understandably enables Pufendorf to maintain that international law is the common link of all men, not merely that of Christendom. In public law, while recognizing the state as a moral person, Pufendorf teaches that the will of the state is but the sum of the individual wills that constitute it, foreshadowing Rousseau and the *Contrat social*.

In 1677 Pufendorf became historiographer royal at Stockholm and thereafter virtually abandoned international and natural law for historical, political and theological studies. To this period belongs (in addition to, e.g., histories of Sweden and the reign of Charles X Gustavus) the *De habitu religionis christianae ad vitam civilem*. This work, in which he traces the limits between ecclesiastical and civil power, was the basis of the *Kollegialsystem* of church government, which, developed by Christoph Plaff (1686–1760), was the basis of church and state relations in Germany.

This theory makes a fundamental distinction between the supreme jurisdiction in ecclesiastical matters (*Kirchenhoheit* or *ius circa sacra*) which is inherent in the power of the state with respect to every religious communion and the ecclesiastical power (*Kirchengewalt* or *ius in sacra*) which belongs to the church but which is, in some cases, vested in the state by the consent—express or tacit—of the ecclesiastical body. Though naturally not accepted by the Roman Catholic Church, the theory did in fact facilitate a working compromise between the Protestant governments and Rome.

In 1686 Pufendorf went to Berlin as historiographer to the great elector of Brandenburg. He was created a baron and died at Berlin in 1694.

The value of Pufendorf's work was much underestimated by posterity. Responsibility for this rests largely with Leibniz, who would never recognize the greatness of one who was ever his adversary and whom he dismissed as *vir parum jurisconsultus et minime philosophus* ("a man not enough of a lawyer and scarcely a philosopher at all"). Modern scholarship, however, while conceding that he is not a pioneer in the category of Francisco de Vitoria and Grotius, recognizes Pufendorf as a classic writer in the field of international law, and his *Jurisprudence* is the standard one for the 17th and 18th centuries.

See also introductions to the translations of *De jure naturae*, *Elementa Jurisprudentiae* and *De officio* in "Classics of International Law."

(J. A. C. T.)

PUFFBALL, the popular name of a group of fungi belong-

ing to the Basidiomycetes (see FUNGI), and so called because of the cloud of dark dustlike spores that is emitted when the mature plant bursts or is struck. Puffballs are seldom abundant but are not uncommon in meadows and woods, and when young resemble white balls, sometimes with a short stalk, and are fleshy in texture. While they are white, solid, and fleshy they are edible.

The giant puffball, *Calvatia maxima*, undoubtedly the largest of all fungi, may sometimes attain a weight of 15 lb. or more and measure up to 2 ft. or more in circumference. Such large specimens may produce billions of spores, only a small fraction of which will ever alight on a

ROCHE

PUFFBALL (LYCOPERDON PERLATUM)

location that is suitable to germination and growth.

PUFFBIRD, the popular name given to the family Bucconidae, of the order Piciformes, because of the habit these birds have of ruffling the loose plumage of the neck and head while perching. The Piciformes includes also woodpeckers, toucans, jacamars, etc. The Bucconidae are confined to tropical America, from southern Mexico to Argentina. Most dwell in lightly forested areas near water; a few live in deep forest. Puffbirds are plainly coloured, and the majority have a spotted or mottled plumage suggestive of immaturity. They feed on insects that they capture on the wing. The smallest, the lance-billed puffbird (*Micromonacha lanceolata*) of northern South America, is five to six inches long. Most puffbirds are very quiet, and apparently use the same hunting perch for months at a time. The black-collared puffbird (*Bucco capensis*) is one of several similar species that occur in northern South America; they all have a prominent black band encircling the body at chest level.

PUFFER, any of certain chiefly marine fishes belonging to the families Diodontidae and Tetraodontidae, which are able to inflate their bodies by swallowing air or water. The common names puffer, balloonfish, and globefish allude to this ability; the

BY COURTESY OF MARINELAND OF FLORIDA

HARBLED PUFFER (SPHAEROIDES DORSALIS): (LEFT) NORMAL STATE; (RIGHT) DISTENDED STATE

names sea hedgehog, burrfish, and porcupine fish are descriptive of certain spiny members. Puffers are most numerous in the tropics, but occur in all warm seas. The jaws of a puffer resemble the beak of a parrot, the bones and teeth being coalesced into a sharp-edged structure that is used to break off branches of corals, and to masticate other hard food substances. The typical puffer is short, thick, and cylindrical, with weak fins. The body is covered with tough, scaleless skin, but is often provided with prickles or spines. When frightened, the fish swallows large quantities of water and assumes a globular form; and spines, if present, protrude to form defensive armour. A puffer held out of water will swallow air and then can float belly upward. Although many puffers contain a deadly poison (tetrodotoxin), the Japanese (who call them *fugu*) prize them as food; specially qualified chefs are not always successful in removing all the toxic dorsal flesh, and many persons die annually from *fugu* poisoning.

(C. HU.)

PUFFIN, a group of comical-looking birds of the auk family (Alcidae), confined to northern oceans and known also as sea par-

rots, bottlenoses, etc. They have characteristically sharp, compressed, triangular beaks. Colonies occur from Arctic coasts southward to Brittany and Maine. Puffins are noted for the punctuality of their return to breeding sites in successive springs. They nest in large colonies on seaside and island cliffs. Puffins usually lay only one egg. They eat a variety of marine organisms. Naturalists are puzzled by the birds' ability to catch as many as ten small fish in succession and to carry them dangling crosswise in the bill to their nestlings.

The common puffin (*Fratercula arctica*), of the Atlantic, is black above, white below, with gray face plumage, orange-red feet, a blue-gray, yellow and red bill, and plates of coloured horny skin around the beak and on the eyelids. These outgrowths are molted after the breeding season. The horned puffin (*F. corniculata*) is a Pacific relative of the Atlantic species. Of more southerly Pacific distribution is the tufted puffin (*Lunda cirrhata*), which is black, with red bill and legs, a white face and straw-coloured plumes curving backward from behind the pale eyes (see also AUK). The generic term *Puffinus* refers to the shearwaters (q.v.). (R. C. MU.)

JOHN MARRHAM

COMMON PUFFIN (FRATERCULA ARCTICA) GATHERING FISH FOR YOUNG

PUGACHEV, EMELYAN IVANOVICH (1742?-1775), famous leader of the greatest Cossack and peasant rebellion in Russian history, was born Zimoveiskaya Stanitsa on the Don River. The son of a Cossack landowner, he was registered at 17 as a member of the Don *voisko*, or army (see COSSACKS), and took part in the final battles of the Seven Years' War (1756-63). In the Russo-Turkish War of 1768-74 Pugachev, then an ensign, was present at the siege and conquest of Bendery (1769-70). Invalided home, for the next three years he led a wandering life, frequenting the monasteries of the Old Believers, who exercised considerable influence over him. When at Mechetnaya Sloboda (later renamed Nikolayevsk and in 1918 Pugachev, Saratov province) he learned about the cruel repression ordered against the Yaik (Ural) Cossack rebellion in 1772. He left for Yaitski (now Uralsk) and discovered among the Cossacks strong anti-government feelings. Arrested as a deserter, he was imprisoned at Kazan and sentenced to be deported to Siberia, but in June 1773 he escaped and in August he appeared in the steppes east of the Volga proclaiming himself to be the emperor Peter III (q.v.). Pugachev asserted that he had escaped from his wife who had ordered his assassination, and was resolved to redress people's grievances, restore their freedom to the Cossacks, and put the empress Catherine II in a monastery.

A man of intelligence and great audacity and a good organizer, Pugachev started his campaign in September with a force of 80 Yaik Cossack rebels. He took by storm the small forts along the Yaik river and on Oct. 16 (new style; 5, old style) started storming the fortress of Orenburg. At that time he had under his command 2,500 men and 20 guns; by December his army had grown to 30,000 with 86 guns. His plan was to conquer Orenburg and then march through Kazan and Moscow to St. Petersburg, but Orenburg resisted and Pugachev made a strategic error by committing the bulk of his forces to the siege. This gave the Russian high command time to send a relief army under Gen. A. I. Bibikov. On April 3 (N.S.), 1774, Pugachev was defeated at Tatishchevo, west of Orenburg. The next day he left northward to Bashkiria whose Turkic inhabitants under Salavat Yulaev joined his forces. Turning westward, he stormed Kazan on July 24 (N.S.), but five days later was defeated by another relief Russian army under Gen. I. I. Mikhelson. With a small detachment of 500 men, Pugachev passed to the right bank of the Volga and marched southward with the hope of starting a rebellion among his Don Cossacks. Joined during his progress by new peasant rebels, he stormed Tsivilsk, Kurmysh, Alaty, Saransk, Penza, Petrovsk and, on Aug. 14 (N.S.), Saratov. Frightened by these successes the

Russian government promised a reward of 28,000 rubles for Pugachev's head and at the same time reinforced the army of Mikhelson that followed the rebels. Pugachev was forced to abandon the siege of Tsaritsyn and on Sept. 3 (N.S.) was finally defeated near Salsnikovaya Vataga 47 mi. S of Tsaritsyn, losing 10,000 in killed and prisoners. Pugachev crossed the lower Volga with a group of loyal followers, planning to spend the winter at Guryev, but he was betrayed by a few Yaik Cossacks and on Sept. 27 (N.S.) was delivered to Gen. A. V. Suvorov at Yaitski. He was brought in an iron cage to Moscow, where he was executed on Jan. 22 (N.S.), 1775.

PUGET, PIERRE (1620–1694), most powerful and original of French Baroque sculptors, was also a painter and architect. He was born at or near Marseilles on Oct. 16, 1620, and traveled in Italy as a young man (1640–43), when he was employed by Pietro da Cortona on the ceiling decorations of the Barberini Palace, Rome, and the Pitti Palace, Florence. Between 1643 and 1656 he was active in Marseilles and Toulon chiefly as a painter, but he also carved colossal figureheads for men-of-war. His first important sculpture commission in 1656 was for the doorway of the Town Hall at Toulon; his caryatid figures there, although in the tradition of Roman Baroque, show a strain and an anguish that mark Puget as a type of provençal Michelangelo.

In 1659 Puget was called to Paris, where he attracted the attention of Louis XIV's minister Fouquet. The latter fell from power in 1661 while Puget was in Italy selecting marble for the Hercules commissioned by him (now the "Hercule gaulois" in the Louvre), and Puget remained in Italy for several years, establishing a considerable reputation as a sculptor in Genoa; a St. Sebastian in S. Maria di Carignano is among his best works there.

After 1669 Puget's life was spent mainly in Toulon and Marseilles, where he was engaged on architectural work and the decoration of ships as well as sculpture. His difficult and somewhat arrogant temperament made him unacceptable to Louis XIV's powerful minister Colbert, and it was only late in life that he achieved some degree of court patronage. His "Milo of Crotona" (1671–84) was taken to Versailles in 1683 and the "Perseus and Andromeda" was well received there in 1684 (both now in the Louvre). But Puget was soon the victim of intrigues by his rivals, and his success at court was short-lived. His fine low relief of "Alexander and Diogenes" (1671–93, Louvre) never reached Versailles, and other works planned for Versailles were either refused or frustrated. Embittered by these failures, Puget died at Marseilles on Dec. 2, 1694. See also **SCULPTURE: Baroque Sculpture**.

PUGILISM; see **BOXING**.

PUGIN, AUGUSTUS WELBY NORTHMORE (1812–1852), English architect, who worked on the designs for the Houses of Parliament, was born in London on March 1, 1812, and died on Sept. 14, 1852, at Ramsgate. In the office of his father, Augustus Charles Pugin, he helped prepare a series of works on the Gothic buildings of England. He was a skilful etcher, and made numerous drawings and sketches, in pen and ink or with sepia monochrome, perfect in their delicacy and precision. After his reception into the Roman Catholic Church in 1833, he became a leader in the English Gothic revival. In 1837–43 he assisted Sir Charles Barry in working out the details for the new Houses of Parliament at Westminster; and though his exact share was the subject of bitter controversy, there is no doubt that the excellence of the details was partly due to him and to his training of the masons and carvers. Many of his executed works, such as the cathedral of St. George at Southwark and the church in Farm Street, Berkeley Square, London, suffered from later alterations. The cathedral of Killarney and the chapel of the Benedictine Monastery of Douai best express his original conception. He also designed his own house at Ramsgate and the stately Adare Hall in Ireland built for Lord Dunraven.

Pugin published *Contrasts; or a Parallel Between the Architecture of the 15th and 19th Centuries* (1836); *True Principles*

of Christian Architecture (1841); *Glossary of Ecclesiastical Ornament* (1844); and *Treatise on Chancel Screens and Rood Lofts* (1851). See also **DESIGN, 19TH CENTURY**.

See B. Ferrez, *Recollections of A. W. Pugin and His Father* (1861); Paul Waterhouse, "The Life and Work of Welby Pugin," *Architectural Review*, iii, iv (1898).

PUGLIA (or **APULIA**), a region of southern Italy, extends from the Fortore River in the northwest to Cape Santa Maria di Leuca, the "heel" of the peninsula, in the southeast. It has a total area of 7,470 sq. mi. (19,347 sq. km.), a population (1961) of 3,309,975, and is composed of the provinces of Bari, Brindisi, Foggia, Lecce, and Taranto (*qq.v.*). The northern third of the region is centred on the Foggia Plain, or Tavoliere, flanked by the Gargano massif in the north and the Neapolitan Apennines in the west. The central third is occupied by the low plateau of the Murge Salentine, limited in the west by a depression, the "fossa premurgiana," while in the east it slopes gradually to the narrow coastal plains of the Adriatic. The southern third, southeast of the Taranto-Ostuni line, is the Salentina Peninsula, consisting of the lowland of Lecce and the low plateaus east of Taranto and south of Lecce. The predominant rock material of Puglia is limestone, and karst phenomena of underground drainage and large cave formations are present in many areas.

The coastline for the most part is low and sandy, except in the Gargano Peninsula and in the southeasternmost tip of Puglia. The only rivers of significance are the Fortore and the Ofanto, but there are numerous springs, some under the sea near the coastline. The absence of surface water over large areas led to the construction of the Apulian Aqueduct, the largest of its kind in Italy, that traverses the entire region as far as Cape Leuca (see **AQUEDUCT**).

Wheat and oats are the principal cereals, raised in the Foggia Plain and in the more fertile parts of the plateaus; olives, grapes, almonds, and figs are grown intensively in the coastal and some inland areas; tobacco is a speciality of the Lecce Plain. The wines of Puglia are among the strongest of Italy and are used to fortify other, lighter varieties. Fishing is carried out in many ports; those of the Gargano, of Barletta, of Monopoli, and of Taranto are the most important. Salt is produced from seawater at Margherita di Savoia, near Foggia. About 1,000,000 sheep once grazed on the plain but owing to cultivation it only supports half that number today. Bari is the largest city and the leading port, as well as the biggest industrial centre (especially chemicals and petrochemicals); other, lesser industries are located in Brindisi, Taranto, and Foggia. The largest railroad centre is Foggia, with lines connecting it to Naples-Rome, Bologna-Milan, and Bari-Taranto-Brindisi-Lecce. The so-called "Ionian" railroad follows the Ionian coast from Taranto to Reggio di Calabria. After World War II Puglia became one of the principal areas of Italian land reform, and numerous small farms were created from the old landed estates, new farm houses and rural service centres built, new roads and aqueducts constructed, transforming the face of the land.

The southeastern extremity of Puglia was Roman (not modern) Calabria. For archaeology, Roman and early history see **APULIA; CALABRIA (ANCIENT)**. After the tumultuous times following the disintegration of the Roman Empire, Puglia was ruled by the Byzantines for over two centuries, and came to know its greatest glory under the Hohenstaufen emperors. It was a favourite of Frederick II (1220–50) and cathedrals and palaces witness the flowering of Puglia at that time. Thereafter a long period of decline set in, accentuated by neglect by distant rulers (Aragonians, Spaniards, Neapolitans) and by slave raids along the coast. In 1860 Puglia became part of the Italian kingdom. (G. KH)

PULA (Italian **POLA**), a seaport of the Socialist Republic of Croatia, Yugos., lies at the southern tip of the Istrian Peninsula at the head of the Bay of Pula, 67 mi. (108 km.) SW of Rijeka by road. Pop. (1961) 37,403 (Croats 63%, total Yugoslavs 79%). The town has a temple of Augustus and Roma and a Byzantine basilica, both restored; also an archaeological museum with Roman and other collections. Pula has a safe, commodious and almost landlocked harbour and is primarily a naval base. It

is the terminus of the railway from Trieste and Ljubljana and linked to these by main roads. It has many industries and ship-building yards.

The history of Pula begins with its capture by the Romans in 178–177 B.C., when it was known as Nesakton. It was destroyed by Augustus because of its support of Pompey but later rebuilt as Pietas Julia. In A.D. 198–211 an amphitheatre more than 400 ft. long and 320 ft. wide was built in honour of emperors Septimius Severus and Caracalla. It could accommodate 23,000 spectators; it is well preserved and is used for summer festivals. In the 2nd century Pula became the seat of a Christian bishop. Byzantium occupied it in 539. In 810 it passed to the Franks and in 1148 to the Venetians. In 1379 the Genoese, after defeating the Venetians in a naval battle nearby, took and destroyed Pula, which then disappeared almost completely from history for more than 400 years. In 1797 the Austrians took the town; in 1809–13 Napoleon occupied it, but in 1819 it reverted to Austria and became the main harbour and arsenal of the Austrian Navy. Under the Rapallo Agreement of 1920 it passed to Italy, and in 1947 to Yugoslavia. (V. DE.)

PULASKI, KAZIMIERZ (CASIMIR) (1747–1779), Polish patriot and U.S. army officer, hero of the Polish anti-Russian insurrection of 1768 and of the American Revolution, was born at Winiary in Mazovia, on March 4, 1747, the son of Jozef Pulaski (1704–69), one of the originators of the Confederation of Bar (q.v.). All Jozef's three sons took part in the confederation's military actions: Franciszek (1745–69) was killed in Lithuania; Antoni (1750–1815) was taken prisoner by the Russians; and Kazimierz distinguished himself by his defense of besieged Berdichev in spring 1768 and later by his guerrilla campaign near the Turkish frontier. In 1769 he valiantly defended Zwaniec and Okopy Swietej Trojcy. On Sept. 10, 1770, he occupied the fortified monastery of Czestochowa, which became the base for extensive operations ranging from the Carpathians to Poznan. The defense of Czestochowa against the Russians brought Pulaski fame in Poland and in western Europe. In October 1771 he set out for Warsaw with the aim of kidnapping King Stanislaw II to the camp of the confederates. The attempt failed (Nov. 3, 1771), and Pulaski was falsely accused of trying to murder the king. In spring 1772, when Prussian and Austrian armies also invaded Poland, the fate of the confederation was sealed; and on May 31 Pulaski left Czestochowa for Saxony, whence he later moved to France. In 1774 he went to Turkey to organize Polish army units there, but Turkey was already on the road to concluding peace with Russia. Returning to France, he lived there in financial straits because of the confiscation of all his estates in Poland.

In December 1776, in Paris, Pulaski was introduced to Benjamin Franklin by Claude de Rulhière; and in June 1777 he landed in America with a letter of recommendation from Franklin to Washington. In Washington's army he served at Brandywine, was made general and chief of cavalry by Congress and fought at Germantown and in the winter campaign of 1777–78. In 1778, as brigadier, he formed a mixed corps, the Pulaski Legion, at the head of which he tried to exploit his experience of guerrilla warfare. In May 1779 he defended Charleston. Wounded at Savannah, Pulaski died on Oct. 11, 1779, aboard the "Wasp" on its way to Charleston.

BIBLIOGRAPHY.—W. Konopczynski, *Kazimierz Pulaski* (1931; Eng. trans. 1947); C. A. Manning, *Soldier of Liberty: Casimir Pulaski* (1945); F. Pulaski (ed.), *Correspondance du général Casimir Pulaski avec Claude de Rulhière* (1948). (EM. R.)

PULCHERIA (399–453), Roman empress, daughter of Arcadius and Eudoxia (q.v.), was born in Constantinople on Jan. 19, 399. Appointed Augusta on July 4, 414, she soon acted as regent for her brother Theodosius II (q.v.), and her court was one of extreme piety and chastity. She quarreled c. 440 with the empress Eudocia (q.v.), her sister-in-law, who left Constantinople forever in 443. When Theodosius II died in July 450, she helped Marcian (q.v.) to succeed him, and she crowned him in the Hebdomon suburb of Constantinople on Aug. 25. She also agreed to become his nominal wife, thus formally preserving the Theodosian dynasty. She was a rigid Catholic and quarreled with the heresi-

arch Nestorius, who repeatedly insulted her. She attended the Council of Chalcedon on Oct. 25, 451, and was loudly acclaimed by the bishops there. She built several churches in Constantinople before she died in 453, leaving all her possessions to the poor. (E. A. T.)

PULCI, LUIGI (1432–1484), Italian poet whose name is chiefly associated with *Morgante*, one of the outstanding epics of the Renaissance, was born in Florence, Aug. 15, 1432. For many years he lived under the protection of the Medici family, especially Lorenzo il Magnifico, who first introduced him into the circle of poets and artists which was gathering round him and later, after assuming power, entrusted him with various embassies and diplomatic missions. Nevertheless, poverty and other hardships caused him, when about 38–40, to enter the service of a northern condottiere, Roberto Sanseverino, with whom he remained until his death at Padua in Nov. 1484.

Pulci's literary output, all in Italian, was very large. Among minor works, his *Lettere* (mod. ed., 1886) and *Sonetti* (mod. ed., 1932) are worthy of mention as revelations of his extravagant character, wide but not always deep cultural interests and biting criticism of contemporary Florentine writers and philosophers. But his masterpiece is the *Morgante* or *Morgante Maggiore*, a chivalrous epic in 23 cantos, later expanded to 28, begun about 1460, of which the earliest surviving complete edition is dated 1483. The plot of the poem is simple. Orlando, the hero, driven from the court of Charlemagne, goes to Paganía, where he meets three giants, two of whom he kills. The third, Morgante, is converted and becomes his faithful squire. Orlando and Morgante are joined by Rinaldo, who has also quarreled with Charlemagne, and the poem then recounts their episodic adventures in Africa and Asia, which continue until Orlando and Rinaldo, hearing that the Saracens have reached the borders of France, hasten to its defense. The story ends with the battle of Roncevaux and the death of Orlando. The predominantly comic and burlesque tone is varied by a more serious mood in which the author expresses at times deep and sincere feeling, at times a bitter experience of life. Similarly, Pulci's amoral attitude, typical of an age which considered success as the only criterion of salvation; contrasts with his deeply felt religious problems, which constitute a large part of the poem. It is this complexity and richness of feeling which makes the *Morgante* both one of the most original poems in Italian literature, and an essential text for understanding of the Renaissance.

Modern editions of the *Morgante* include those by G. B. Weston (1930), G. Fatini (1948) and F. Ageno (1955).

PULITZER, JOSEPH (1847–1911), U.S. editor and newspaper proprietor, was born in Mako, Hungary, April 10, 1847. Educated privately in Budapest he was induced by a U.S. agent to emigrate as a recruit for the Union army. He was discharged from the army on July 7, 1865, and went to St. Louis, where he arrived penniless. In 1868 he became a reporter on the German-language daily newspaper, the *Westliche Post*. He was elected in 1869 to the lower house of the Missouri legislature, where he gained a reputation as a reformer, and in 1871–72 he helped organize the Liberal Republican party in Missouri and was one of the secretaries of the Cincinnati convention that nominated Horace Greeley for president.

Pulitzer became a newspaper proprietor in 1871 by buying a share of the *Westliche Post* on liberal terms. This he soon re-

THE BETTMANN ARCHIVE, INC.

JOSEPH PULITZER

sold for \$30,000, using part of the proceeds for an extended tour of Europe. On his return in 1874 he purchased a moribund German daily, the *St. Louis Staats-Zeitung*, and sold its Associated Press franchise to the *Globe* for \$20,000. In 1878 he laid the foundation of his fortune by purchasing at auction the dying *St. Louis Dispatch*, and merging it with the *St. Louis Post* as the *Post-Dispatch*, which soon dominated the St. Louis evening field. The paper was independent in politics and devoted to "hard money" and tariff reform. In 1880 Pulitzer became sole owner, but unfortunately in Oct. 1882 his chief editorial aid, Col. John A. Cockerill, shot and killed Col. Alonzo W. Slayback, a lawyer, in a bitter political quarrel. Public reprobation was so great that the *Post-Dispatch* lost revenue and Pulitzer departed for the east in the spring of 1883, where he bought the *New York World* from Jay Gould for \$346,000.

Under its new management the *World* won prosperity, its annual earnings by 1886 rising to more than \$500,000. In 1887 Pulitzer established the *Evening World*. To the *World*, as to the *Post-Dispatch*, Pulitzer gave a tone of aggressive editorial independence. He supported Grover Cleveland for the presidency in 1884, 1888 and 1892. He was sympathetic to labour; in 1892 he took the side of the striking steel workers at Homestead, Pa. He opposed William Jennings Bryan for the presidency in 1896 and became an advocate of war with Spain.

The *World* was largely responsible for bringing on the New York state legislative investigation of insurance companies in 1905. In 1909 the U.S. government successfully sought an indictment against Pulitzer for criminally libeling Pres. Theodore Roosevelt, J. P. Morgan, Elihu Root and others in connection with allegations about the disposition of the \$40,000,000 paid the French Panama Canal Co. The case was never prosecuted.

In his later years Pulitzer's health compelled him to live as an invalid, but he kept in intimate touch with the *World* until within a few weeks of his death in Charleston, S.C., Oct. 29, 1911.

Pulitzer was elected to the U.S. house of representatives from New York in 1885, and served briefly in congress. During his lifetime he endowed the school of journalism of Columbia university, opened in 1912. He also established the Pulitzer prizes, awarded annually for fiction, drama, history, biography, poetry, music and various categories of newspaper work.

Tebbel, *Makers of Modern Journalism* (1952); E. H. Ford and E. Emery, *Highlights in the History of the American Press* (1954).

PULKOVO, a village in Leningrad oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies 11 mi. (17 km.) S of Leningrad on the road to Gatchina, beside the city airport. The village is notable for the location there of the chief astronomic observatory of the Academy of Sciences of the U.S.S.R. Opened in 1839, it was designed by the architect A. P. Bryullov. It was destroyed in World War II but was afterward rebuilt. Up to the Revolution Russian maps were based on the Pulkovo meridian, 30°19'39" east of Greenwich. (R. A. F.)

PULLEY AND BELT, a mechanical arrangement for transmitting torque from one shaft to another. The torque originates at a wheel or drum, called the drive pulley, that applies torque to a continuous, flexible member called the belt. The belt passes around and delivers torque to a second wheel or drum, called the driven pulley.

A pulley may be made fast to a shaft by a setscrew or key in the pulley hub, or by a tapered bushing drawn between shaft and hub; or the pulley may turn freely on a shaft as an idler. Pulley rim and hub may be one solid piece connected by a flange, web or tapered arms, depending on the pulley diameter. Pulleys whose peripheral surfaces are grooved are called sheaves.

Belt drives are used when one or more of the following conditions prevail: (1) The distance between shafts is large; (2) flexibility is desired to absorb shock; (3) overloads can be absorbed by belt slippage without damaging machine parts; (4) low cost is desired; (5) quietness is desired.

Belts are suitable for approximate velocity ratios only, because overload causes slippage between the surfaces of the belt and each

pulley; even when slippage does not occur, creep takes place. Creep is a small backward movement of the belt relative to the pulley because of belt elasticity. The higher tension of the belt (T_1) reduces to the lower tension (T_2) as the belt travels around the drive pulley (see fig. 1), hence the length of belt leaving the pulley is less than the length entering. Creep alone reduces operating speed about 1%, and slippage causes loss of another 2%.

In addition, excessive slippage causes belt damage. Belts are operated at about 5,000 ft. per minute; above this speed most of the belt strength is needed to withstand the tension from the centrifugal force rather than the load.

Both tight (T_1) and slack (T_2) sides of the belt pull on the pulley and result in a net force of their difference ($T_1 - T_2$) act-

FIG. 1.—BELT ON PULLEYS

Solid pulley (at right) is driving a larger pulley (at left) with rim connected to hub by arms. In arranging pulleys, the slack side of the belt should be on top to increase angles of contact. (See text)

ing at the pulley surface to produce torque. The torque is dependent upon the ratio of effective forces which according to theory is $\frac{T_1 - T_c}{T_2 - T_c} = e^{f\alpha/\sin \theta}$, where T_c is centrifugal force of one

foot of belt, $e = 2.718$, f is the coefficient of friction between surfaces and α is the angle of contact in radians between belt and pulley, and θ is one-half the groove angle. The maximum value of T_1 is limited by the tensile strength of the belt.

Transmissive capacity is dependent upon the effective force ($T_1 - T_2$), hence will be greatest when the ratio of effective tensions, equal to $e^{f\alpha/\sin \theta}$, is greatest. The frictional resistance to slip depends upon the coefficient of friction, the normal contact force and the angle of contact between belt and pulley. Combinations of materials, form of belt and angle of contact are selected to give the required capacity.

Types of Belts.—Belts are made of any material having suitable strength and flexibility and of any shape resistant to slipping (fig. 2). Combinations of material and cross section used are: flat leather operating on a flat or crowned pulley; round leather wedged in grooves of a sheave; V-belts or trapezoidal or sharp V-section consisting of cotton cords, cotton sheets or steel wire vulcanized in rubber with a sheave; woven fabric on a pulley; spiral steel spring with a sheave; flat steel on a pulley for high speeds; hemp or Manila rope wedged into sheave grooves; stranded steel rope resting without wedging in the padded bottom of grooves in a sheave.

Leather Belts.—Leather belts of best quality are made of strips from the rear, back and sides of steer hides. The hide is cleaned, cured, dehaired, defleshed and then tanned in a solution of tannin to make the leather strong and pliable. Oak bark is used to produce a tannite solution in which the hides are cleaned, worked "stuffed" with grease and stretched. Mineral salts such as chromium salts may be used for tanning. Chrome-tanned leather has greater tensile strength, a higher coefficient of friction (particularly until oak-tanned leather is used a while), greater flexibility and greater resistance to water, steam and certain chemicals. It is, however, softer than oak-tanned leather and lacks the lateral stiffness required to shift a belt by applying force at its edge. Combinations of oak and chrome tanning give a product with some of the advantages of each.

After preparation, the centre portion of the hide, which possesses the tightest texture, is cut into strips and squared. Pieces are then selected according to soundness and thickness. The

pieces are scarfed to a feather edge and cemented together under pressure to make a continuous roll of belt. Belts of hide thickness are called "single ply." Double ply and triple ply belts for heavier loads are made by cementing together a number of strips. Belt thickness depends upon the hide thickness and varies from $\frac{1}{8}$ to $\frac{3}{4}$ in. for single ply, $\frac{1}{4}$ to $\frac{3}{8}$ in. for double ply, and $\frac{1}{8}$ to $\frac{1}{4}$ in. for triple ply.

Oak-tanned belting is the most generally used leather belt. Sandwiches of oak- and chrome-tanned belting have been used for special purposes, but such combinations are rare. Leather is used also for round belts, V-belts and link belts composed of overlapping leather links connected by steel pins.

Rubber Belts.—Rubber belts are made of natural and synthetic rubber, generally in combination with a load-carrying core. Flat belts are composed of plies (or layers) of cotton duck impregnated with a slow-aging rubber compound. Most generally used weight is 32 oz. cotton duck. The duck is folded to the desired number of plies and then vulcanized together. The rubberized cords may be left exposed or encased in a protective covering of rubber. Other constructions use load-carrying members of parallel longitudinal cords of fabric or steel within a vulcanized rubber covering. Strength is about 325 lb. per ply per inch.

V-belts of rubber are made of layers of duck or of various combinations of cotton cords encased in a rubber body of trapezoidal cross section, the strength of the belt depending upon the fabric rather than upon the belt cross section. The layer type has raw edges, whereas the cord type body is covered with a rubberized fabric.

Because the V-belt is stiff due to its depth, some constructions flute the inner edge to give flexibility without sacrificing contacting surface. Endless V-belts are molded in a press with five standard cross-section sizes available in various lengths. Multiple V-belt drives use a number of parallel belts of the same length running in parallel grooves in the pulley face. The belt does not bottom in the groove. Unreinforced rubber belts of round cross section are used for light loads where considerable elasticity is desired.

Other Types of Belts.—Balata belting is similar in construction to rubber belting. Balata is a gum from the bullet tree (*Manihara bidentata*, formerly known as *Mimusops balsa*) of Guiana and the West Indies. The belting is nonelastic and can be made waterproof.

Steel bands, carefully made and balanced, may be used as belts on accurately aligned pulleys. The high strength-weight ratio of steel allows large force transmission at high speeds with a relatively small reduction from centrifugal force.

Belt Fasteners.—Belt lengths may be connected by the following separate fastenings, accompanied, however, by a reduction in strength as indicated: machine wire lacing, 10%; hand wire lacing, 18%; lacing with rawhide strips, 40%; metal hooks, 65%.

Metal belt loops are bent into the end of each belt, the hooks placed side by side and a pin of leather or steel inserted through the loops to provide a connecting pivot. A stamped sheet may be used instead of separate wires.

The belt must be stretched over the pulleys and made into a continuous strip. The joint may be cemented together in position by stretching with screw clamps and cementing the prepared ends together. Cemented joints develop practically the full strength of the belt, which is about 4,000 lb. per square inch. The maximum working load is usually limited to about 400 lb. per square inch for safety.

Construction and Stresses of Pulleys.—Pulleys are usually made in one piece of cast iron. The hub has an outside diameter about twice the bore and is fastened to the shaft by a key, setscrew or compression bushing. The width of the hub is approximately the same as the width of the pulley. The hub is connected to the rim by arms that are elliptical in cross section and tapered from hub to rim. The rim surface is adapted to the form of belt used.

Because of centrifugal force the rim, if free, is subjected to a tensile hoop stress of $\frac{12wv^2}{g}$ where w is the weight of one square inch of section, v is the rim velocity in feet per second, and g

is 32.2 ft. per second per second. For cast iron this stress in pounds per square inch is closely $\frac{v^2}{10}$. The rim is partially restrained by the arms and so is subjected to a lesser hoop stress but, consequently, also to a bending stress. The resultant stress is difficult to assess but is greater than the full free hoop stress alone. An unannealed pulley contains shrinkage stresses of unknown amount, so a close calculation of working stress is of little practical use. The arms should be sufficient in number to limit the unsupported length of rim. Four to six arms are sufficient in most instances.

Surface speeds of cast iron pulleys are usually limited to 4,000 ft. per minute. Under favourable conditions webbed cast iron pulleys might be used up to 10,000 ft. per minute. Wooden built-up pulleys of maple have been used for high speeds because wood is lighter for its strength than cast iron. Pressed steel

FIG. 2.—BELT AND PULLEY FORMS

(A) flat belt on crowned pulley; (B) V-belt on sheave; (C) round belt on sheave; (D) steel rope on sheave

pulleys are lightweight and have a high strength-weight ratio but are more easily deformed because of the thin sections of which they are made.

Motor pulleys are made of wood, rawhide or pressed paper held between metal end plates. The diameter of a pulley for leather belts is recommended to be not less than 30 times the belt thickness to limit the flexing of the belt as it goes on and off the pulley. The rim of a pulley for a flat belt is made slightly wider than the belt. For cylindrical pulleys in the same plane the belt must be of the same length along each edge and must be mounted on pulleys which are properly aligned. If the pulley centres are not parallel the belt will ride toward the tight side and off the pulley. The belt lies flat on the pulley surface and, because of its lateral stiffness, is tilted toward the high side of the pulley. Thus each successive point of the approaching belt is nearer to the high end of the pulley face. Drive pulleys are crowned by being made with a larger diameter at mid-section; the crown amounts to about $\frac{1}{8}$ in. per foot of width and makes the belt run centrally (fig. 2). Thus the pulley surface is geometrically two slight cones base to base, and the belt rides to the greatest diameter in mid-face. Idler pulleys and pulleys on which the belt is shifted are not crowned.

Belt Arrangements.—An open belt arrangement rotates the driven pulley in the same direction as the driver. Crossed belts cause the driven pulley to rotate opposite to the driver. A crossed belt has considerably greater contact angle than an open belt, hence will transmit greater torque. Such an arrangement is usually avoided, however, because the belt surfaces rub together at the point of crossing and cause wear.

Pulleys with shaft centres in the horizontal plane transmit the greatest torque. As the line between centres departs from the horizontal the transmissible capacity is reduced. The slack side should be on top so that sag in the belt will increase the angle of contact.

Belts afford a simple means of connecting shafts which are not in the same plane. In order for the belt to stay on the pulleys the centre line of the approaching belt must lie in the centre plane of the approached pulley. This

FIG. 3.—BELT CONNECTING SHAFTS IN DIFFERENT PLANES

arrangement is shown in fig. 3. Note that if the direction of belt travel is reversed the required relationship is no longer satisfied and the belt will run off the pulley.

The addition of an idler pulley in accordance with the above rule would permit travel in either direction.

V-belt sheaves have grooves of the same angle as the belt section used with them. The grooves are deeper than the belt so that it contacts the sides but not the bottom. Wide wedge-shaped belts are used between adjustable sides so that as the sides are moved apart the belt lies lower on the sides and the pitch diameter decreases. As the lie of the belt is lowered, the belt velocity must be increased if the angular velocity of the pulley is to remain the same.

Belt Adjustments.—Short-centre drives are frequently employed when an electric motor is used to drive a machine. The small angle of contact on the smaller pulley caused by the short centre distance of the pulley limits the torque that can be transmitted. The driving motor may be mounted on a base that can be adjusted by a screw so the permanent stretch of the belt may be taken up by separating the pulleys. This adjustment can be made only occasionally and does not maintain tightness because the belt length changes elastically with load. One method of maintaining tightness and increasing the angle of contact is to use a gravity- or spring-loaded idler pulley. Another method is to use a motor base pivoted so the weight of the motor produces balancing tensions on the belt in an amount equal to the desired maximum capacity. The tight side of the belt should be between the pivot and the pulley centre. (E. S. A.)

PULLMAN, GEORGE MORTIMER (1831–1897), U.S. industrialist and inventor of the Pullman car, was born at Brocton, Chautauqua County, N.Y., on March 3, 1831. He moved to Chicago in 1855, accumulated some capital as a contractor, and began to work on his earlier idea of devising a better sleeping car. The first real Pullman car appeared in 1865, embodying Pullman's conviction that if he produced something better than anyone else, regardless of expense, someone would pay the price. He was president of the Pullman Palace Car Company, organized in 1867, which built cars and operated Pullmans under contracts with railroads. His widely discussed social experiment, a paternalistic model town for his workmen, located south of Chicago, came to grief when a strike broke out that precipitated the great Pullman strike of Eugene Debs's American Railway Union in 1894. The state later forced the company to give up control of the town. Pullman died on Oct. 19, 1897.

BIBLIOGRAPHY.—George A. Mortimer, in *Dictionary of American Biography*, vol. xv (1935); Almont Lindsey, *The Pullman Strike* (1942), includes critical appraisals of Pullman and his model town; Joseph Husband, *The Story of the Pullman Car* (1917), is laudatory.

PULP: see PAPER MANUFACTURE.

PULPIT, a raised platform with enclosed front, from which sermons are delivered. The pulpit probably derived from the ambo (*q.v.*) in the early Christian church. There are many old pulpits of stone, though the majority are of wood. Those in churches are generally hexagonal or octagonal; some stand on stone bases, and others on slender wooden stems, like columns. The designs vary according to the periods in which they were erected, having paneling, tracing, cusplings, crockets, and other ornaments. Some are extremely rich and ornamented with colour and gilding. A few also have rich canopies or sounding boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Outdoor pulpits were common in the medieval period, and stood near a road or cross. Pulpits, for reading during the meals of the monks, are found in refectories. After the Reformation the English canons ordered pulpits to be erected in all churches. Many of the time of Elizabeth I and James are beautifully carved, and of Flemish workmanship. The pulpits in mosques, known as "minbars," are canopied and approached by a straight flight of steps. These have a doorway at the foot, with an enriched lintel and boldly molded head; the work is of wood, often inlaid, gorgeously painted and gilded.

PULQUE, the typical indigenous beer of the peasant and poorer urban classes of the central and northern Mexican high-

lands. For many, it is an important source of carbohydrates, amino acids, and vitamins. For the populations of some arid regions, such as the valley of the Mezquital, it may supply most of the fluid intake in some seasons.

Pulque is the freshly fermented sap of any of ten or more of the larger species of agave or maguey plants, particularly *Agave atrovirens* in the valley of Mexico, which are cultivated in household plantings and large commercial plantations. (See AGAVE.) To collect the sap (*agua miel*), a cavity is made in the apex of the short fleshy stem of a four- to six-year-old plant by cutting out the emerging flower shoot. Three or four months later, the cavity walls and surrounding leaf bases are scraped, after which the first sap is drawn. The cavity refills two or three times daily, producing 10 to 15 pints of sap a day until the plant dies.

The sap, which contains about 10% of sugars, is taken to processing centres where, after several days of fermentation, it becomes *pulque*. The fermentation process is usually hastened by adding old *pulque* (*madre pulque*), a starter or inoculum rich in yeasts and lactic acid bacteria. Other additives may be employed to the same end. The result of this accelerated fermentation is *pulque fuerte*; probably most *pulque* is produced in this way. The fresh product is dispensed from barrels in drinking houses or is sold in containers; some is pasteurized and bottled.

The alcohol content varies from less than 1% to 5%; the less alcoholic *pulque* is consumed as a soft drink. A sour buttermilk-like taste is imparted by lactic acid; viscosity results from mucilaginous materials in the *agua miel* and from bacterial action; the whitish appearance is due to suspended yeast and plant cells. *Pulque curado* contains added flavouring; *pulque curado de fresa*, for example, contains strawberry (*fresa*) flavouring. (L. K.)

PULVERIZED FUEL: see FUELS.

PUMA (*Felis concolor*), which occurs only in the western hemisphere, is exceeded in size among cats of the new world only by the jaguar. Besides the term puma, which is derived from usage by the Incas of South America, it is also known by the following names: cougar, deer tiger, Mexican lion, panther, painter (corruption of panther), mountain lion, and catamount. At least 15 subspecies of the puma are recognized; they range widely, from British Columbia in the north to Patagonia in the south, and formerly ranged coast to coast from the Atlantic to the Pacific. Man has eliminated pumas in many locations; they are now generally restricted to wilderness areas away from dense human populations.

A wide range of coloration exists among puma, from pale buff to reddish brown. The ears and tip of the tail are generally dark, while the rump and the belly, extending to the first hind leg joints, are white. There is no mane. Weights of adult puma range from about 75 to 275 lb.; shoulder height may be 2–2½ ft., the males being larger than the females. From one to six kittens are produced after a gestation period of 90–96 days; they may be born in any month of the year. The young have rows of small, irregular black spots, which disappear at maturity.

The puma exists on a wide range of foods, its favourite, when available, being deer. When killing, the puma brings its victim to the ground with the stunning impact of its entire weight, generally attacking at the throat and breast. See also CAT. (S. P. Y.)

PUMICE, a very porous, frothlike, volcanic glass. Pumice has long been used as an abrasive, in cleaning, polishing and scouring compounds. After 1945 its uses multiplied in applications as railroad ballast and as a lightweight aggregate in precast masonry units, poured concrete, insulation and acoustic tile and plaster.

Pumice is an igneous rock which was almost completely liquid at the moment of effusion and was so rapidly cooled that there was

W. L. MILLER FROM NATIONAL AUDUBON SOCIETY

PUMA OR MOUNTAIN LION (*FELIS CONCOLOR*)

no time for it to crystallize. When it solidified the vapours dissolved in it were suddenly released and the whole mass swelled up into a froth which immediately consolidated. Had it cooled under more pressure it would have formed a solid glass or obsidian (q.v.); in fact if fragments of obsidian are heated in a crucible till they fuse they will suddenly change to pumice when their dissolved gases are set free. Hence it can be understood that pumice is found only in recent volcanic countries. Any type of lava, if the conditions are favourable, may assume the pumiceous state; but basalts and andesites do not so often occur in this form as do trachytes and rhyolites.

Pumices are most abundant and most typically developed from acid rocks, for which reason they usually accompany obsidians; in fact, in the Italian island of Lipari and elsewhere the base of a lava flow may be black obsidian while the upper portion is a snow white pumice.

Small crystals of various minerals occur in many pumices; the most common are feldspar, augite, hornblende and zircon. The cavities of pumice are sometimes rounded, and may also be elongated or tubular owing to the flowing movement of the solidifying lava. The glass itself forms threads, fibres and thin partitions between the vesicles. Rhyolite and trachyte pumices are white, contain 60% to 75% of silica and the specific gravity of the glass is 2.3 to 2.4; andesite pumices are often yellow or brown; while pumiceous basalts, such as occur in the Hawaiian Islands, are pitch black when perfectly fresh.

Good pumice is found in Iceland, Hungary, Tenerife Island in the Canaries, New Zealand, Pantelleria Island and the Lipari Islands of Italy, West Germany and Greece. In the United States pumice is mined in the Rocky mountain and Pacific coast states (as Arizona, California, Nevada, New Mexico, Wyoming), and Hawaii. Pumice occurs among the older volcanic rocks, but usually has its cavities filled up by deposits of secondary minerals introduced by percolating water. Pumice, in minute fragments, has been shown to have an exceedingly wide distribution over the earth's surface. It occurs in all the deposits which cover the floor of the deepest portion of the oceans, and is especially abundant in the abysmal red clay. In some measure this pumice has been derived from submarine volcanic eruptions, but its presence is also accounted for by the fact that pumice will float on water for months, and is thus distributed over the sea by winds and currents. After a long time it becomes waterlogged and sinks to the bottom, where it gradually disintegrates and is incorporated in the muds and ooze which are gathering there. After the great eruption of Krakatau (q.v.) in 1883, banks of pumice covered the surface of the sea for many miles and rose in some cases for four or five feet above the water level. In addition much finely broken pumice was thrown into the air to a great height and was borne away by the winds, ultimately settling down in the most distant parts of the continents and oceans. See also TUFF; VOLCANO.

(J. S. F.; X.)

PUMP, a device for increasing the pressure of a fluid, usually a liquid. The increase in pressure, or head, is used to move the fluid through some channel or to raise it to a higher level, or both. Pumps are used in many applications: e.g., to deliver water for home and industrial use; to transport oil across the country; to circulate oil, water and fuel in automobiles, airplanes and other vehicles; to lift a barber's chair; and in many industrial plants where fluids are used for power transmission or in manufacturing processes. In a pump, mechanical work is transformed into fluid energy; by contrast, in a turbine, fluid energy is transformed into mechanical work at some rotating shaft.

Pumps may be divided into two main types: the positive-displacement or static type; and the dynamic or kinetic type. In the positive-displacement type the characteristic action is a displace-

ment by a decrease in volume in the working chamber of the pump. The increase in fluid static pressure is developed by a displacement action rather than by a velocity change or a kinetic energy change. The reciprocating pump, the rotary pump, the gear pump and the vane pump are illustrations of positive-displacement pumps. In the kinetic or dynamic type there is a kinetic or dynamic action between some mechanical element and a fluid; a force acting on the fluid causes a significant velocity change. The centrifugal pump and the jet pump are examples of the dynamic type.

Reciprocating Pumps.—In the common reciprocating pump a piston moves back and forth in a cylinder. An example is the hand bicycle pump, in which, as the hand pushes the piston back and forth, air from the atmosphere enters the cylinder and is pushed out of the cylinder into the tire by the piston action. Suitable valves are necessary to control the flow properly. Fig. 1 illustrates the case in which the piston is moved back and forth in the cylinder by an arrangement of crank and connecting rod. As the piston moves toward the right, the outlet check valve is open, the inlet valve is closed, and the fluid flows from the cylinder through the outlet or discharge pipe. As the piston moves toward the left, the inlet check valve is open, the outlet valve is closed, and fluid enters the cylinder. If leakage past the piston is neglected, then the piston delivers the volume of fluid it displaces in moving through the cylinder; this explains the term positive-displacement.

A single-acting pump, in which fluid is pumped only by one side of the piston is illustrated in fig. 1. This can be turned into a double-acting pump—in which both sides of the piston are in contact with the fluid, and both sides pump—simply by adding inlet and outlet pipes, with suitable valves, at the other end of the cylinder (and, of course, providing a proper seal at the opening where the piston rod enters the cylinder).

For a given volume rate of flow through the pump, the pressure at the pump outlet may be high or low, depending on the pressure necessary to force the fluid through the system connected to the pump; thus the discharge pressure is governed by the load or piping system. The pressure that a reciprocating pump can develop is limited only by the strength of the pump components and the power of the driving unit.

On some reciprocating pumps there is an air chamber on the discharge. The air trapped in the chamber acts as a cushion, making the pump operation smooth and quiet. Generally speaking, reciprocating pumps are best adapted for relatively low rates of flow, high pressures and high suction lifts. They are built of a wide variety of materials and for many different types of service. Reciprocating pumps are not well suited for pumping very dirty or very viscous liquids, because of the possibility of clogging.

Various methods are used for reciprocating the piston, such as different mechanical linkages or a fluid under pressure. For example, steam may be used on one side of the piston to drive it while water or some other liquid is pumped by the other side.

Diaphragm Pumps.—If, instead of the movable piston in fig. 1 a circular diaphragm—of rubber or other flexible material—is fixed at its outer edge to the cylinder, and if the crank and connecting rod linkage is fastened at its centre, the result will be a diaphragm pump. The central portion of the diaphragm is moved back and forth to provide volumetric displacement, and the inlet and outlet valve arrangement is similar to that of the reciprocating pump. Because there is no possibility of liquid bypassing the diaphragm and coming in contact with the connecting rod or other pump parts, diaphragm pumps are used for handling such materials as thick pulps, sewage sludge, acids, alkaline solutions, mine waters and fruit juices.

Rotary Pumps.—The rotary pump is classed as a positive-displacement pump, although its action is one of rotation, not reciprocation. It should not be confused with the centrifugal pump. The gear pump in fig. 2, an example of one type of rotary pump, has a pair of meshed gears in a casing. As the gears rotate, fluid is caught between their teeth and the casing, and is carried from inlet to outlet, the volume of fluid delivered during each revolution depending on the amount of space between the teeth

FIG. 1.—RECIPROCATING PUMP

RIGHT, AFTER E. F. WRIGHT, "PUMPS," "MECHANICAL ENGINEERS' HANDBOOK"; REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK COMPANY

FIG. 2.—SCHEMATIC DIAGRAM OF (A) ROTARY PUMP; (B) HYDRAULIC VANE PUMP OR MOTOR; (C) LOBE PUMP

and the case. Delivery is fairly steady, in contrast to the pulsating delivery of the reciprocating pump.

Rotary pumps are most suitable for applications requiring only low and medium delivery pressure. The absence of valves is an advantage in pumping heavy viscous liquids but because of the close clearances between gears and case, rotary pumps are not suitable for liquids containing any abrasive material that might damage the metal surfaces.

Different types of rotary pumps are available. In some pumps, rotating members with two or more lobes are used instead of gears. In the vane type of pump, there is a rotor set off-center in a casing. The rotor is fitted with vanes which slide in and out radially. The entering liquid is trapped between the vanes, which ride on the inside of the case, and is carried to the outlet.

Centrifugal Pumps.—The essential parts of a centrifugal pump are a rotating member with blades or vanes (the so-called impeller) and a case surrounding it. The action in a centrifugal pump depends upon centrifugal force or a variation of pressure due to rotation.

As shown in fig. 3, fluid is led through the inlet pipe to the centre or "eye" of the rotating impeller; it is thrown out at high velocity through the impeller vanes and into the volute, the spiral casing surrounding the impeller. The volute is designed so that its cross-sectional area increases constantly toward the outlet, and this has the effect of changing the high-velocity, low-pressure stream leaving the impeller into a low-velocity, high-pressure stream at the outlet.

Centrifugal pumps are made with various arrangements of impellers. Fig. 3 shows a so-called "single-suction" pump: fluid enters from only one side of the impeller. Fluid enters both sides of the impeller in a so-called "double-suction" pump. A pump may be in "stages," with several impellers on a single shaft; in a three-stage pump, for example, three impellers are mounted on the same shaft in one casing. The discharge from one impeller enters the inlet of a following impeller. The same weight of fluid per unit time passes through each stage, but each stage increases the pressure. In the radial-flow impeller shown in fig. 3, fluid enters the impeller at the hub and flows radially along the blade to the periphery; in a mixed-flow impeller, fluid flow is along the blade (radial) and across it (parallel to the axis of shaft rotation).

Centrifugal pumps differ from positive-displacement pumps in

FIG. 3.—CENTRIFUGAL PUMP

various ways. As an illustration, the discharge valve of a centrifugal pump can be closed without the pressure rising above a certain value; if the discharge valve of a reciprocating pump is closed, the pump will stall or some part of it will break. The flow from a centrifugal pump is relatively smooth and steady, and these pumps can handle various liquids, sewage and liquids containing sand, gravel and stones of moderate size.

Centrifugal pumps are sometimes classified as volute or diffuser types. Fig. 3 shows a volute type: the fluid being discharged directly from the impeller into the volute. In the diffuser type, there is a series of fixed vanes, surrounding the impeller, that reduce turbulence in the volute by smoothing the flow of fluid and lowering its velocity; there is a decrease in kinetic energy and an increase in static pressure in the volute diffuser.

Axial-flow Pumps.—An axial-flow pump is a dynamic machine which may consist of a single runner in a cylindrical casing or of a runner with one or two sets of fixed guide vanes. In an axial-flow pump the fluid passes through the runner without essentially changing its distance from the axis of rotation (in principle and design, the axial-flow pump is much like a gas turbine). There is practically no centrifugal force effect within the true axial-flow pump. Generally speaking, the centrifugal pump is best suited for producing relatively high pressure and low rates of flow, while the axial-flow pump is best for producing relatively low pressures and high rates of flow.

Deep-Well Pumps.—Various types of pumps have been developed for pumping water or oil from deep wells. One, called the plunger pump, is essentially a reciprocating pump with a long piston rod. In the so-called turbine deep-well pump, a motor at the surface turns a vertical rotating shaft; this shaft drives a multistage centrifugal pump (with impellers rotating in a horizontal plane) which is installed in the well below the surface of the water or oil. For high lifts, the pump may have 20 or more stages.

Fig. 4 illustrates a submersible motor pump; the elongated, small-diameter electric motor operates submerged in the well liquid. The liquid being pumped does not come in contact with the electric parts or motor bearings, because these are enclosed in an oil-filled case which has a mercury seal where the rotating shaft passes through the top to the pump.

The pump and motor form a compact assembly that is fastened to and supported by the outlet pipe. A liquid-tight armored cable connects the motor leads to the power supply at the surface and a small copper tube provides a lubrication inlet at the surface for larger models; small models are provided with "permanent" lubrication and require no attention.

Each type of deep-well pump has its advantages. For a specific application in a well of moderate depth, the plunger pump usually is least expensive; and since it is the only one of the three that can be operated directly by a windmill it has often been used in remote locations. As in the case with the turbine pump, the power source is at the surface and readily accessible for maintenance. However, in both cases, trouble with the pumping unit necessitates withdrawing and disconnecting section by section the plunger rod or turbine shaft, to raise the pump to the surface; this is true also of the submersible-motor pump.

The limit of depth at which the plunger pump will operate economically is reached when the power unit is expending almost as much, or more, energy lifting a long plunger rod than lifting fluid; and this type of pump does not work well except in very straight well bores. The economical limit of the turbine pump is reached when more energy is expended in overcoming bearing friction in the long shaft than in lifting fluid (the shaft must be supported at frequent intervals by "spiders" or frameworks that fit against the sides of the well bore and are fitted with bearings to keep the shaft centred in the bore); the turbine pump will work in an out-of-plumb well, but any deviation from straightness increases frictional losses at the bearings.

The submersible-motor pump overcomes some of these disadvantages (it will work in a very crooked bore, for example, the amount of deviation being limited only by the angle through which the pump unit and outlet pipe can be inserted and withdrawn easily), but it introduces disadvantages of its own. Principal among these is the fact that malfunctioning of either the pump or the motor necessitates withdrawing the entire unit from the well for repair.

Jet Pumps.—In the reciprocating, rotary and centrifugal pumps, there is a moving mechanical part which does work on the moving fluid. However, there is a dynamic type of pump which does not have any moving mechanical parts: it is called variously a jet pump, injector or ejector. In this type of pump the pressure of a fluid is increased as it flows through an arrangement of fixed channels. A "motive fluid" is used to pump, or induce the flow of, some other fluid.

Jet pumps are found in many applications, pumping many different fluids. A common type is one in which water is the motive fluid and water is the fluid being pumped; such pumps are used on domestic water well systems. As illustrated in fig. 5, water passes through the converging nozzle with a high velocity and acts as a motive or driving fluid; at the end of the nozzle the velocity is high and the pressure is low. The mixture of motive fluid and liquid being pumped, or induced, then passes through the diffuser where the velocity is reduced and the pressure is increased.

A number of pumping devices can be explained by reference to the venturi tube. As illustrated in fig. 6, the venturi tube consists of a converging nozzle and a narrow portion or throat. As motive fluid passes through the converging portion, the velocity is increased and the pressure is decreased, and this decrease in pressure can be used to move some other fluid. In the usual aspirator pump, water passes through a venturi channel, and air is drawn into the venturi throat by the low pressure; in the common atomizer, air passing through a venturi tube lifts liquid from the

attached container, mixes with the liquid, and ejects it as a fine spray.

Air or Gas Lift Pumps.—In this type of pump there is a vertical lift pipe arranged with its lower end submerged in the liquid to be raised and its upper end connected to a discharge pipe or tank. Air or gas from a compressor is led through a separate pipe to the lower end of the lift pipe, where it bubbles through the liquid to form a gas-liquid mixture that has a lower density (or specific weight) than the surrounding liquid. The resulting buoyant force moves the lighter mixture (of gas and liquid) to the top of the vertical pipe. In this type of pump, air may be used to pump water, or a gas may be used to pump oil. The pumping action depends on the air or gas used, the nature of the liquid, the depth of submersion of the lower end of the lift pipe, and the manner of forming the bubbles.

Vacuum Pumps.—Atmospheric pressure is the force exerted on a unit area due to the weight of the atmosphere. The word "vacuum" is frequently used in referring to pressures below atmospheric. In many cases it is desired to exhaust or evacuate air (or some gas) from a vessel or a piece of equipment. The aspirator pump can be used to develop a partial vacuum; other types, to produce higher degrees of vacuum, are described in the article VACUUM.

Magnetic Pumps for Liquid Metals.—Certain characteristics of liquid metals make them attractive as heat-transfer liquids for cooling nuclear reactors. The electromagnetic pump has proved suitable for the circulation of some of these liquid metals. The electromagnetic pump uses the same principle on which the electric motor is based; namely, that a conductor in a magnetic field, carrying a current flowing at right angles to the magnetic field direction, has a force exerted on it in a direction mutually perpendicular to both the field and current. In the electromagnetic pump, the fluid being pumped is the conductor, and the resultant force acts to propel the fluid if suitable arrangements are made. The current and field can be produced in many ways. In one electromagnetic pump, the D.C.-Faraday type, the liquid metal flows through a thin-walled duct of square or rectangular cross-section. A constant magnetic field is passed through the fluid on an axis perpendicular to the flow direction. The magnetic field is developed by windings, carrying direct current, that are mounted on a magnetic core with pole faces that provide a magnetic return path through the fluid metal. Current is passed through the fluid by establishing a voltage drop along the axis of the duct, mutually perpendicular to both the flow direction and the magnetic field direction. In theory, the operation of this pump is similar to that of a direct-current shunt motor.

PUMPKIN, the fruit of certain varieties of *Cucurbita pepo* or of *C. moschata*, members of the family Cucurbitaceae. The names pumpkin and squash, especially in America, are applied inconsistently to certain varieties of both these species. The quick-growing, small-fruited bush or nontrailing varieties of *C. pepo* (see SQUASH) are called squash in America, while the long-season, long-trailing, large-fruited varieties are called pumpkin.

The fruits are large, generally 10–20 lb. or more, yellowish to orange in colour, and vary from oblate through globular to oblong. The rind is smooth and usually lightly furrowed or ribbed; the fruit stem is hard and woody, ridged or angled, and in *C. pepo* not flared at its point of attachment to the fruit. The very largest varieties of "pumpkin" are more properly designated as winter squash, *C. maxima*, and may weigh 75 lb. or more. Varieties cross-pollinate readily within each of the three species, but the species do not cross naturally. A few interspecific crosses have been recorded but the hybrids were highly self-sterile and set no fruit

with their own pollen. Neither pumpkins nor squashes will cross with cucumbers or with melons.

The varieties commonly called pumpkin produce very long vines and are usually planted in hills of two to three plants each, about eight by eight feet apart. They are also planted at wide intervals in fields of corn. Pumpkins mature in early fall and can be stored a few months in a dry place well above freezing.

Pumpkins are commonly grown in North America, Great Britain, and Europe for human food and also for livestock feed. The rind is peeled and cooked for use as a vegetable dish or in puddings or pies. Pumpkins are used in the U.S. as Halloween decorations, one such being the jack-o'-lantern, in which the pulp of the pumpkin is removed and a light inserted to shine through cutout eyes, nose, and mouth.

(V. R. B.)

PUN, a witty play upon two or more meanings for the same word, or on two words with identical sounds. Example: "She was a good cook as cooks go, and as cooks go, she went."—H. H. Munro. This form of wit has been in and out of fashion many times. It was highly respected in Shakespeare's age, but Oliver Wendell Holmes, the poet, dubbed it "the lowest form of wit"—in which he freely indulged. It can be used seriously, as metaphor, as when Emerson says the poet "apprises us not of his wealth, but of the common wealth." With mingled humour and pathos Shakespeare declared: "Golden lads and girls all must, / As chimney-sweepers, come to dust." See **FIGURES OF SPEECH: Play Upon Words**.

(G. W. A.)

PUNAN, the name applied to a number of peoples in middle Borneo (*q.v.*), all of them, except the Punan Ba (a branch of the Kajang), traditionally forest nomads in the mountainous areas around the upper reaches of the major rivers. The majority are now agricultural. Those still nomadic live in isolated groups averaging about 35 individuals, subsisting on the wild sago palm and on game hunted, until very recently, with blowpipe and spear. Physically and culturally they are very similar to other mongoloid peoples of this part of the island; none of them is Negrito or demonstrably aboriginal in Borneo.

The Punan peoples speak mutually unintelligible languages; and employ various means of exploiting the environment; but they resemble each other in degree of civilization, their general mode of social life, and the egalitarian sharing of foodstuffs.

As a result of the common name applied to these groups, accounts of Punan are confused and misleading. The only nomads who have received attention from ethnographers are those in the Baram area, whose correct name is in fact Penan. These comprise two tribes that have no corporate unity; there is little recognition of common interest beyond directly related groups, and the group has no chief. Their traditional life is simple: they live in flimsy huts, have few belongings, wear only a loincloth, and are almost devoid of ceremony. They differ from the settled peoples mainly in their economy, lack of class stratification, and absence of any trace of a head-hunting cult. About three times a year they descend to fixed points on the rivers to trade with their hereditary overlords in the riverine tribes, exchanging forest products (chiefly dammar resin and wild rubber) for metal tools, cloth, household utensils, and tobacco. Individual groups adopt words and customs from different surrounding settled peoples, whom they tend increasingly to resemble.

There are about 2,600 Penan. The number of Punan cannot be exactly computed, but is probably not more than another 2,000.

PUNCH, the abbreviated form of **PUNCHINELLO** (Italian *Polichinello*, *Pulcinella*; French, *Polichinelle*), the most popular of the marionettes and glove puppets and the chief figure in the Punch and Judy show. Many modern authorities tend to accept the opinion that the whole family of Italian *maschere* (masked characters of the *commedia dell'arte*; e.g., Arlecchino and Brighella) are modified survivals of the principal Oscan characters of the *atellanae*, and that *Pulcinella* is the representative of *Maccus*, the country bumpkin, or *Bucco*, the comic servant (see **ATEL-**

LANA FABULA). But there is a gap of 1,000 years between the last records of the Atellan farces and the first of the *commedia dell'arte*, and it would be ingenious to follow the antiquaries of the 18th century in accepting a clear connection between the two. At the same time it is interesting to compare a bronze of *Maccus* with 17th-century pictures of *Pulcinella* in Italy and France.

It is not certainly known who was the first *Pulcinella*. Claims have been made on behalf of Silvio Fiorillo and Andrea Calcese, both of whom were performing at the beginning of the 17th century. But some facts of his early history are definite. One of the *zanni*, the comic serv-

vants of the company, he was indispensable when the troupe played in Naples but did not always appear in other localities. His characteristics were not clearly marked at first, and the hooked nose, the humped back, the tendency to wife-beating and outrageous lawlessness typical of the English Punch were acquired only gradually. This is clearly seen from the first pictorial representations. The earliest, in which he is called *Polichinello*, is dated 1618 and is one of a series made from birds' feathers by Dionisio Minaggio, the gardener of the governor of Milan. The second, in 1622, is of *Pulcinello* in Jacques Callot's *I Balli di Sfessania*. In both he is depicted as large, shambling and stupid-looking, dressed in a loose white shirt and very full trousers.

The Italian actors soon began to travel abroad. A few of them were in Nottingham, Eng., in 1573. The *Gelosi*, one of the most famous companies, visited Paris in 1577. It is not known exactly when *Pulcinella* arrived in these countries but the French version, *Polichinelle*, was firmly established in France by the middle of the 17th century. When the actors came from Italy the puppet showmen came with them. By 1649 a showman called Jean Brioché, probably an Italian named Briocci, was displaying a puppet *Polichinelle* near the Pont Neuf in Paris. The marionette was grotesque, humpbacked and hook-nosed, but its origin may not have been entirely Italian. There was a French tradition of hunchbacked fools, as can be seen from a print of the entertainment at the marriage of Henry IV with Marie de Médicis in 1600, and the popularity of the *Polichinelle* puppet in France may be due to the fusion of these two traditions.

Similarly a tradition of the humpbacked fool existed in England when the first Italian puppeteers arrived after the restoration of Charles II. In 1662 a showman called Signor Bologna, alias *Polichinella*, was performing in London, and by 1667 a more elaborate entertainment of *Punchinello* was established at Charing Cross by Antonio Devoto. In 1672 the king gave his patronage to the theatre, and then performances with human actors were permitted. Already the shortened form of the name had passed into general usage.

Samuel Pepys mentions (1669) some people who called their fat child Punch, "that word being become a word of common use for all that is thick and short." This general popularity was probably caused by the traveling showmen, who carried puppeteers to the country wakes in the summer and visited London for the fairs in August and September.

Early in the 18th century Punch became famous in political circles through the use of the name by Martin Powell, a marionette showman, in a scurrilous attack on Robert Harley. This pamphlet, entitled *A Second Tale of a Tub* (1715), furnishes some details of Punch performances and has a frontispiece of Powell with Punch and his wife. But it was in the 1790s that the revival occurred which caused the preservation of Punch and Judy: as the marionettes at the fairs lost their popularity, there was a new interest in the humbler glove puppets, and in this form the

Punch and Judy play became a success. *See also* **COMMEDIA DELL'ARTE**; **PUPPETRY**.

PUNCHING AND SHEARING MACHINES: *see* **MACHINE TOOLS**.

PUNIC WARS, a name specially given to the wars between Rome and Carthage in the 3rd and 2nd centuries B.C. The origin of these conflicts is to be found in the position which Rome acquired, about 275 B.C., as leader and protector of all Italy. The attendant new obligation to safeguard the peninsula against foreign interference made it necessary not to allow the neighbouring island of Sicily to fall into the hands of a strong and expansive power. Carthage, on the other hand, had long been anxious to conquer Sicily and so to complete the chain of island posts by which it controlled the western Mediterranean.

First Punic War (264–241 B.C.).—The proximate cause of the first outbreak was a crisis in the city of Messana (Messina), commanding the straits between Italy and Sicily. A band of Campanian mercenaries, the Mamertini, who had forcibly established themselves within the town and were being hard pressed in 264 by Hieron II of Syracuse, applied for help to both Rome and Carthage. The Carthaginians, arriving first, occupied Messana and effected a reconciliation with Hieron. The Roman commander, nevertheless, persisted in throwing troops into the city, and by seizing the Carthaginian admiral during a parley induced him to withdraw. This aggression involved war with Carthage and Syracuse.

Operations began with a joint attack upon Messana, which the Romans easily repelled. In 263 they advanced with a considerable force into Hieron's territory and induced him to seek peace and alliance with them. In 262 they besieged and captured the enemy's base at Agrigentum. But they made little impression upon the Carthaginian fortresses in the west of the island and upon the towns of the interior.

In 260 the Romans built their first large fleet of standard battleships. At Mylae (Milazzo), off the north Sicilian coast, their admiral Gaius Duilius defeated a Carthaginian squadron of superior maneuvering capacity by grappling and boarding. This left Rome free to land a force on Corsica (259) and expel the Carthaginians, but did not suffice to loosen their grasp on Sicily. A large Roman fleet sailed out in 256, repelled the entire Carthaginian fleet off Cape Ecnomus (near modern Licata) and established a fortified camp on African soil at Clypea (Kelibia in Tunisia). The Carthaginians, whose citizen levy was utterly disorganized, could neither keep the field against the invaders nor prevent their subjects from revolting. After one campaign they were ready to sue for peace, but the terms which the Roman commander M. Atilius Regulus offered were intolerably harsh. Accordingly they equipped a new army in which, by the advice of a Greek captain of mercenaries named Xanthippus, cavalry and elephants formed the strongest arm. In 255, under Xanthippus' command, they offered battle to Regulus, who had taken up position with an inadequate force near Tunis, outmaneuvered him, and destroyed the bulk of his army. A second Roman fleet which subsequently reached Africa after defeating the full Carthaginian fleet off Cape Hermaeum (Cape Bon), withdrew all the remaining troops.

The Romans now directed their efforts once more against Sicily. In 254 they captured the important fortress of Panormus (Palermito), but when Carthage threw reinforcements into the island the war again came to a standstill. In 251 or 250 the Roman general L. Metellus at last brought about a pitched battle near Panormus in which the enemy's force was effectively crippled. This victory was followed by an investment of the chief Punic base at Lilybaeum (Marsala), together with Drepanum (Trapani), land and sea. The besiegers met with a gallant resistance, and in 249 were compelled to withdraw by the loss of their fleet in a surprise attack upon Drepanum, in which the admiral P. Claudius Pulcher was repulsed with a loss of 93 ships. This was the

Romans' only naval defeat in the war but their fleet had suffered a series of grievous losses by storm, and now it was so reduced that the attack upon Sicily had to be suspended. At the same time the Carthaginians, who felt no less severely the financial strain of the prolonged struggle, reduced their forces and made no attempt to deliver a counterattack. The only noteworthy feature of the ensuing campaigns is the skilful guerrilla war waged by a new Carthaginian commander, Hamilcar Barca, from his strong positions on Mt. Ercte (247/246–244) and Mt. Eryx (modern Erice) (244–242) in western Sicily, by which he effectually screened Lilybaeum from any attempt on it by the Roman land army.

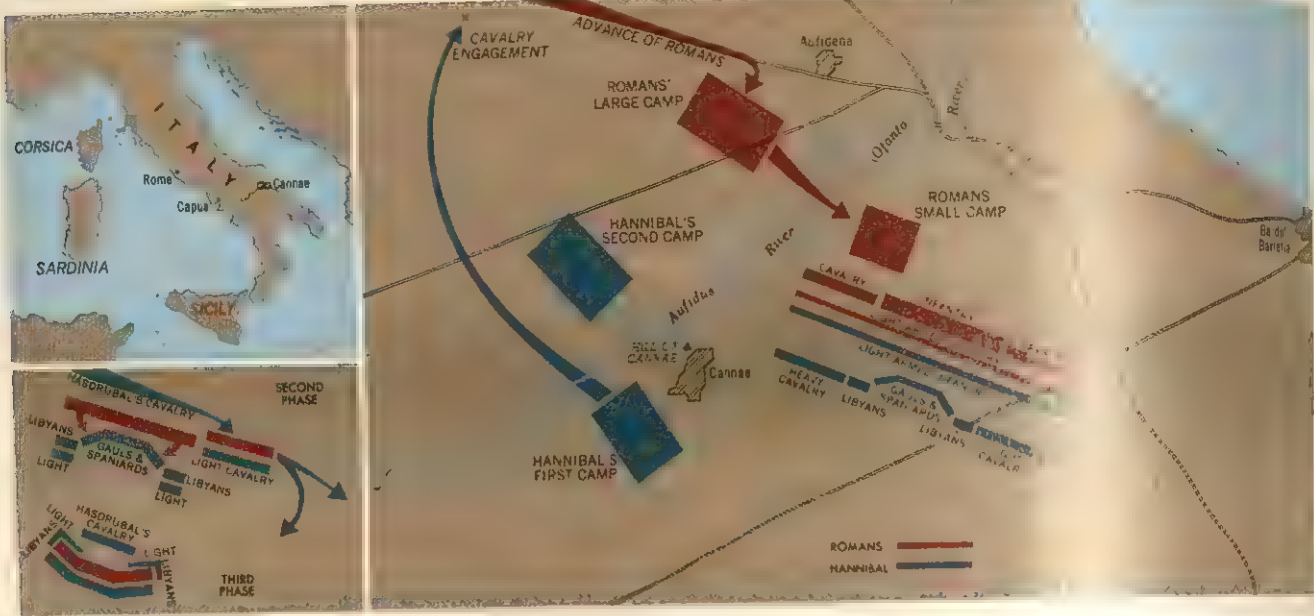

In 242 Rome resumed operations at sea. By a magnificent effort on the part of private citizens a fleet of 200 warships was equipped and sent out to renew the blockade of Lilybaeum. The Carthaginians hastily collected a relief force, but in a battle fought off the Aegates or Aegusae Islands (Aegadian Is.), west of Drepana, their fleet was caught at a disadvantage and mostly sunk or captured (March 10, 241). This victory, by giving the Romans undisputed command of the sea, rendered certain the ultimate fall of the Punic strongholds in Sicily. The Carthaginians accordingly opened negotiations and consented to a peace by which they ceded Sicily and the Lipari Islands to Rome and paid an indemnity of 3,200 talents.

The Interval Between the First and Second Wars (241–218 B.C.).—The loss of naval supremacy not only deprived the Carthaginians of their predominance in the western Mediterranean, but exposed their overseas empire to disintegration under renewed attacks by Rome. The temper of the Roman people was soon made manifest during a conflict which broke out between the Carthaginians and their discontented mercenaries. A gross breach of the treaty was perpetrated when a Roman force was sent to occupy Sardinia, whose insurgent garrison had offered to surrender the island (238). To the remonstrances of Carthage the Romans replied with a direct declaration of war, and only withheld their attack upon the formal cession of Sardinia and Corsica and the payment of a further indemnity.

From this episode it became clear that Rome intended to use the victory to the utmost. To avoid complete humiliation Carthage had no resource but to humiliate its adversary. The recent complications of foreign and internal strife had indeed so weakened the Punic power that the prospect of renewing the war under favourable circumstances seemed remote enough. But the scheme of preparing for a fresh conflict found a worthy champion in Hamilcar Barca, who sought to compensate for the loss of Sicily by acquiring a dominion in Spain where Carthage might gain new wealth and form a fresh base of operations against Rome. Invested with an unrestricted foreign command, he spent the rest of his life in founding a Spanish empire (237–228). His work was continued by his son-in-law Hasdrubal and his son Hannibal, who was placed at the head of the army in 221. These conquests aroused the suspicions of Rome, which in a treaty with Hasdrubal confined the Carthaginians to the south of the Ebro. At some point also Rome entered into relations with Saguntum (Sagunto), a town on the east coast, south of the Ebro. In 219 Hannibal laid siege to Saguntum and carried the town in spite of a stubborn defense.

It has always been a debatable point whether his attack contravened the new treaty. The Romans certainly took this view and sent to Carthage to demand Hannibal's surrender. But his defiant policy was too popular to be disavowed; the Carthaginian council upheld Hannibal's action, and drew upon itself a declaration of war.

Second Punic War (218–201 B.C.).—It seemed as though the superiority of the Romans at sea must enable them to choose the field of battle. They decided to embark one army for Spain and another for Sicily and Africa. But before their preparations were complete, Hannibal began that series of operations by which he dictated the course of the war for the greater part of its duration. Realizing that so long as the Romans commanded the resources of an undivided Italian confederacy no foreign attack could beat them down beyond recovery, he conceived the plan

PLAN OF THE BATTLE OF CANNAE, 216 B.C.

A major battle of the Second Punic War (218–201 B.C.) in which Hannibal was victorious over the Romans. Inset at lower left shows the second and third phases of the battle.

of cutting off their supply of strength at the source by carrying the war into Italy and causing a disruption of the league. His chances of ever reaching Italy seemed small, for the sea was guarded by the Roman fleets and the land route was long and arduous.

But the very boldness of his enterprise contributed to its success; after a six months' march through Spain and Gaul and over the Alps, which the Romans were nowhere in time to oppose, Hannibal arrived in the plain of the Po with 20,000 foot and 6,000 horse, the pick of his African and Spanish levies (autumn 218; for details see HANNIBAL).

His further advance was here disputed by some Roman troops, but the superiority of the Carthaginian cavalry and the spread of insurrection among the Gaulish inhabitants forced the defenders to fall back upon the Apennines. At the end of the year the Roman Army was reinforced by the division from Sicily and led out to battle on the banks of the Trebbia (*q.v.*). Hannibal, by superior tactics, repelled the assailants with heavy loss, and thus made his position in north Italy secure.

In 217 the campaign opened in Etruria, into which the invading army, largely reinforced by Gauls, penetrated by an unguarded pass. A rash pursuit by the Roman field force led to its being entrapped on the shore of Lake Trasimene (Trasimeno, *q.v.*) and destroyed with a loss of at least 15,000 men. This catastrophe left Rome completely uncovered; but Hannibal, having resolved not to attack the capital before he could collect a more overwhelming force, directed his march toward the south of Italy, where he hoped to stir up the peoples who had formerly been Rome's most stubborn enemies. The Italians, however, were everywhere slow to join the Carthaginians, and a new Roman army under the dictator Q. Fabius Maximus ("Cunctator"), which, without ever daring to close with Hannibal, dogged his steps on his forays through Apulia and Campania, prevented his acquiring a permanent base of operations.

The eventful campaign of 216 was begun by a new aggressive move on the part of Rome. An exceptionally strong field army, estimated at 85,000 men, was sent to crush the Carthaginians in open battle. On a level plain near Cannae (*q.v.*) in Apulia, which Hannibal had chosen for his battleground, the Roman legions delivered their attack. Hannibal deliberately allowed his centre to be driven in by their superior numbers, while Hasdrubal's cavalry wheeled round so as to take the enemy in flank and rear. The Romans, surrounded on all sides and so cramped that their superior numbers aggravated their plight, were practically anni-

hiliated, and the loss of citizens was perhaps greater than in any other defeat that befell the republic.

The moral effect of the battle was no less momentous. The south Italian peoples at last found courage to secede from Rome, the leaders of the movement being the people of Capua, at the time the second greatest town of Italy. Reinforcements were sent from Carthage, and several neutral powers prepared to throw their weight into the scale on Hannibal's behalf. At first sight it seems strange that the Battle of Cannae did not decide the war. But the great resources of Rome, though terribly reduced in respect to both men and money, were not yet exhausted. In north and central Italy the insurrection spread but little, and could be sufficiently guarded against with small detachments. In the south the Greek towns of the coast remained loyal, and the numerous Latin colonies continued to render important service by interrupting free communication between the rebels and detaining part of their forces.

In Rome itself the quarrels between the nobles and commons, which had previously unsettled Roman policy, gave way to a unanimity unparalleled in the annals of the republic. The guidance of operations was henceforth left to the Senate, which by maintaining a persistent policy until the conflict was brought to a successful end earned its greatest title to fame.

The subsequent campaigns of the war in Italy assume a new character. Though the Romans contrived at times to raise 200,000 men, they could spare only a moderate force for field operations. Their generals, among whom the veterans Fabius and M. Claudius Marcellus frequently held the most important commands, rarely ventured to engage Hannibal in the open and contented themselves with observing him or skirmishing against his detachments. Hannibal, whose recent accessions of strength were largely discounted by the necessity of assigning troops to protect his new allies or secure their wavering loyalty, was too weak to undertake a vigorous offensive. In the ensuing years the war resolved itself into a multiplicity of minor engagements, which need not be followed out in detail. In 216 and 215 the chief seat of war was Campania, where Hannibal, vainly attempting to establish himself on the coast, experienced a severe repulse at Nola.

In 214 the main Carthaginian force was transferred to Apulia in hopes of capturing Tarentum (Taranto). Though Crotona and Locri on the southern coast had fallen into his hands, Hannibal still lacked a suitable harbour by which he might have secured his overseas communications. For two years he watched

in vain for an opportunity to surprise the town, while the Romans narrowed down the sphere of revolt in Campania and defeated other Carthaginian commanders.

In 213/212 the greater part of Tarentum and other cities of the southern seaboard at last came into Hannibal's power. But in 212 the Romans found themselves strong enough to place Capua under blockade. They severely defeated a Carthaginian relief force, and could not be permanently dislodged even by Hannibal himself. In 211 Hannibal made a last effort to relieve his allies by a feint upon Rome itself, but the besiegers refused to be drawn away from their entrenchments, and eventually Capua was starved into surrender.

Its fall was a sign that no power could in the long run uphold a rival Italian coalition against Rome. After a year of desultory fighting, the Romans in 209 gained a further important success by recovering Tarentum. Though Hannibal still won isolated engagements, he was slowly being driven back into the extreme south of the peninsula.

In 207 the arrival of a fresh invading force produced a new crisis. Hasdrubal, who in 208-207 had marched overland from Spain, appeared in northern Italy with a force scarcely inferior to the army which his brother had brought in 218. After levying contingents of Gauls and Ligurians, he marched down the east coast with the object of joining his brother in central Italy for a direct attack upon Rome itself. By this time the steady drain of men and money was telling so severely upon the confederacy that some of the most loyal allies protested their inability to render further help. Yet by exerting a supreme effort the Romans raised their war establishment to the highest total yet attained and sent a strong field army against each Carthaginian leader.

The danger to Rome was chiefly averted by the prompt insight and enterprise of the consul Gaius Nero, who commanded the main army in the south. Having discovered that Hannibal would not advance beyond Apulia until his brother had established communications with him, Nero slipped away with part of his troops and arrived in time to reinforce his colleague Livius, whose force had recently got into touch with Hasdrubal near Sena Gallica (Senigallia).

The combined Roman army frustrated an attempt of Hasdrubal to elude it and forced him to fight on the banks of the Metaurus (Metauro). The battle was evenly contested until Nero by a dexterous flanking movement cut the enemy's retreat. Hasdrubal himself fell, and the bulk of his army was destroyed.

The campaign of 207 decided the war in Italy. Though Hannibal still maintained himself for some years in southern Italy, this was chiefly due to the exhaustion of Rome after the prodigious strain of past years and the consequent reduction of Roman forces. In 203 Italy was finally cleared of Carthaginian troops. Hannibal, in accordance with orders received from home, sailed back to Africa, and another expedition under his brother, Mago, which had sailed to Liguria in 205 and endeavoured to rouse the slumbering discontent of the people in Cisalpine Gaul and Etruria, was forced to withdraw.

Campaigns in Sicily and Spain.—Concurrently with the great struggle in Italy the Second Punic War was fought out on several other fields. It will suffice merely to allude to the First Macedonian War (214-205) which King Philip V commenced when the Roman power seemed to be breaking up after Cannae. This compelled the Romans to stretch their already severely strained resources still further by sending troops to Greece, but the diversions which Roman diplomacy provided for Philip in Greece and the maintenance of a patrol squadron in the Adriatic Sea prevented any effective cooperation on his part with Hannibal.

In view of the complete stagnation of agriculture in Italy the Romans had to look to Sardinia and Sicily for their food supply. Sardinia was attacked by Carthaginians in 215, but a small Roman force sufficed to repel the invasion. In Sicily a more serious conflict broke out. Some isolated attacks by Punic squadrons were easily frustrated by the strong Roman fleet. But in 215 internal complications arose. The death of Hieron II, Rome's

steadfast friend, left the kingdom of Syracuse to his inexperienced grandson Hieronymus. Flattered by the promises of Carthaginian emissaries, the young prince abruptly broke with the Romans, but before hostilities commenced he was assassinated. The Syracusan people now repudiated the monarchy and resumed their republican constitution, but, by false threats of terrible punishment at the hands of Rome, they were misled to play into the hands of the Carthaginians.

The attacks of a Roman army and fleet under Marcellus which speedily appeared before the town were completely baffled by the mechanical contrivances of the Syracusan mathematician Archimedes (213). Meantime, the revolt against Rome spread in the interior, and a Carthaginian fleet gained control of towns on the south coast.

In 212 Marcellus at last broke through the defense of Syracuse and in spite of the arrival of a Carthaginian relief force mastered the whole town in 211. A guerrilla warfare followed in which the Carthaginians maintained the upper hand until in 210 they lost their base at Agrigentum. They were dislodged from their remaining positions, and by the end of the year Sicily was wholly under the power of Rome.

The conflict in Spain was second in importance to the Italian war alone. From this country the Carthaginians drew large supplies of troops and money which might serve to reinforce Hannibal; hence it was in the interest of the Romans to challenge their enemy within Spain. Though the force which Rome at first spared for this war was small in numbers and rested entirely upon its own resources, the generals Publius and Gnaeus Scipio by skilful strategy and diplomacy not only won over the peoples north of the Ebro and defeated the Carthaginian leader Hasdrubal Barca in his attempts to restore communication with Italy, but carried their arms along the east coast into the heart of the enemy's domain.

But eventually their successes were nullified by a rash advance. Deserted by their native contingents and cut off by Carthaginian cavalry, among which the Numidian prince Masinissa rendered conspicuous service, the Roman generals were killed and their troops destroyed (211).

Disturbances in Africa prevented the Punic commanders from exploiting their success. Before long the fall of Capua enabled Rome to transfer troops from Italy to Spain, and in 210 the best Roman general of the day, the young son and namesake of P. Scipio, was placed in command. He signaled his arrival by a bold and successful *coup de main* upon the great arsenal of Carthago Nova (Cartagena) in 209. Though after an engagement at Baecula (Bailen; 208) he was unable to prevent Hasdrubal Barca from marching away to Italy, Scipio profited by his departure to push back the remaining hostile forces the more rapidly. A last effort by the Carthaginians to retrieve their losses with a fresh army was frustrated by a great victory at Ilipa (*q.v.*), near Seville, and by the end of the year 206 they had been driven out of Spain.

The War in Africa.—In 205 Scipio, who had returned to Rome to hold the consulship, proposed to follow up his victories by an attack upon the home territory of Carthage. Though the presence of Hannibal in Italy deterred Fabius and other senators from sanctioning this policy, Scipio gradually overbore all resistance. He built up a force which he organized and supplemented in Sicily, and in 204 sailed across to Africa. He was there met by a combined levy of Carthage and King Syphax of Numidia, and for a time penned to the shore near Utica. But in the winter he extricated himself by a surprise attack upon the enemy's camp, which resulted in the total loss of the allied force by sword or fire.

In the campaign of 203 a new Carthaginian force was destroyed by Scipio on the Great Plains 75 miles from Utica, their ally Syphax was captured, and the renegade Masinissa (*q.v.*) re-instated in the kingdom from which Syphax had recently expelled him. These disasters induced the Carthaginians to sue for peace, but before the very moderate terms which Scipio offered could be definitely accepted, a sudden reversal of opinion caused them to recall Hannibal's army for a final trial of war and to break off

negotiations. In 202 Hannibal assumed command of a composite force of citizen and mercenary levies stiffened with a corps of his veteran Italian troops.

After an abortive conference with Scipio he prepared for a decisive battle (*see* ZAMA, BATTLE OF). Scipio's force was somewhat smaller in numbers, but well trained throughout and greatly superior in cavalry. His infantry, after evading an attack by the Carthaginian elephants, cut through the first two lines of the enemy, but was unable to break the reserve corps of Hannibal's veterans. The battle was ultimately decided by the cavalry of the Romans and their new ally Masinissa, which by a maneuver recalling the tactics of Cannae took Hannibal's line in the rear and completely destroyed it.

The Carthaginians having thus lost their last army again applied for peace and accepted the terms which Scipio offered. They were compelled to cede Spain and the Mediterranean islands still in their hands, to surrender their warships, to pay an indemnity of 10,000 talents within 50 years, and to forfeit their independence in affairs of war and foreign policy.

The Second Punic War, by far the greatest struggle in which either power engaged, had thus ended in the complete triumph of Rome. This triumph is not to be explained in the main by any faultiness in the Carthaginians' method of attack. The history of the First Punic War, and that of the Second outside of Italy, prove that the Romans were irresistible on neutral or Carthaginian ground. Carthage could only hope to win by invading Italy and using the enemy's home resources against him. The failure of Hannibal's brilliant endeavour to realize these conditions was not due to any strategical mistakes on his part. It was caused by the indomitable strength of will of the Romans, whose character during this period appears at its best, and to the compactness of their Italian confederacy, which no shock of defeat or strain of war could entirely disintegrate.

It is this spectacle of individual genius overborne by corporate and persevering effort which lends to the Second Punic War its peculiar interest.

The Third Punic War (149-146 B.C.)—The political power of Carthage henceforth remained quite insignificant, but its commerce and material resources revived in the 2nd century with such rapidity as to excite the jealousy of the growing mercantile population of Rome and the alarm of its more timid statesmen. Under the influence of these feelings the conviction—sedulously fostered by Cato the Censor—that "Carthage must be destroyed" overbore the scruples of more clear-sighted statesmen. A *casus belli* was readily found in a formal breach of the treaty, committed by the Carthaginians in 150, when they resisted Masinissa's aggressions by force of arms. A Roman army was dispatched to Africa, and although the Carthaginians consented to make reparation by giving hostages and surrendering their arms, they were goaded into revolt by the further stipulation that they must emigrate to some inland site where they would be debarred from commerce.

By a desperate effort they created new war equipment and prepared their city for a siege (149). The Roman attack for two years completely miscarried, until in 147 the command was given to a young officer who had distinguished himself in the early operations of the war—Scipio Aemilianus, the adopted grandson of the former conqueror of Carthage. Scipio made the blockade stringent by walling off the isthmus on which the town lay and by cutting off its sources of supplies from overseas. His main attack was delivered on the harbour side, where he effected an entrance in the face of a determined and ingenious resistance. The struggle did not cease until he had captured house by house the streets that led up to the citadel.

Of a city population perhaps exceeding a quarter of a million, only 50,000 remained at the final surrender. The survivors were sold into slavery; the city was razed to the ground and its site condemned by solemn imprecations to lie desolate for ever. The territory of Carthage, which had recently been much narrowed by Masinissa's encroachments, was converted into a Roman province under the name of "Africa."

PUNJAB, the traditional name of a large region in the northwest of the India-Pakistan subcontinent and formerly a province of British India. Punjab signifies "five waters" or "five rivers," and refers to the Jhelum, Chenab, Ravi, Beas, and Sutlej (*q.v.*) rivers, all of which unite to form the Panjnad (Panchnad) which in turn joins the Indus. The name was applied primarily to the triangle of country, mainly alluvial plains, between the Indus and the Sutlej and stretching northward to the base of the Himalayas.

From 1848 to August 1947, the Punjab formed a British Indian province, the boundaries of which were frequently changed. For a long time the province included the greater part of northwestern India beyond the Jumna (Yamuna) River and Delhi. From its territories the North-West Frontier Province was created to the west of the Indus in 1901 and the Delhi Enclave in the southeast in 1912. In 1937 the province was accorded a large measure of autonomy. Within the provincial boundaries as then defined lay the very large princely state of Bahawalpur (*q.v.*) in the southeast, while in the east were the important state of Patiala (*q.v.*) and a large number (41) of smaller ones.

With the partition of the Indian subcontinent in 1947, the province was also divided into two parts, the larger West Punjab with Bahawalpur, falling to Pakistan and the smaller East Punjab, with Patiala and the numerous east Punjab states, to India. The boundary was drawn by Sir Cyril (later Lord) Radcliffe on the basis of Hindu-Muslim majorities and followed no natural features, cut indiscriminately across rail and road networks, and disrupted the irrigation systems on which the country depended. The water question remained undecided until 1960 (*see* INDIA-PAKISTAN, SUBCONTINENT OF).

Later both India and Pakistan changed the names of their provinces to Punjab. At the time of the 1951 census the area of Pakistani Punjab (excluding Bahawalpur) was 62,245 sq.mi. (161,215 sq.km.); pop. 18,828,015. The area of Indian Punjab was 37,378 sq.mi. (96,809 sq.km.); pop. 12,641,205. In October 1955 the provincial divisions of West Pakistan, including the Punjab, were abolished as administrative units. Thus Punjab, in Pakistan, now remains the name of a region only and not of an administrative area. The Indian Punjab forms a constituent state of India and is the only remaining political entity bearing this name. (*See* also PUNJAB [India] below.)

The economic history of the region in modern times has been the struggle to control the waters of the great rivers. In the south the land fades into the margins of the Thar (Indian) Desert; on the plains in the north parallel to the Himalayan foot-

hills winter cyclonic rain gives better conditions but in many places sudden irregular floods, causing streams draining the Himalayan slopes to burst their banks, formerly resulted in much damage and consequent famine. The gradual development of great perennial irrigation canals using the Jumna and each of the five rivers of the Punjab was one of the great triumphs of the British period of the 19th–20th century. It permitted much expansion of cultivation and many new settlements resulted in a great rise in population.

(K. S. Ad.; L. D. S.)

History.—The history of the Punjab has been profoundly influenced by the fact that between Peshawar and Dera Ismail Khan the four frontier passes of the Khyber, Kurram, Tochi, and Gumal serve as gateways from Afghanistan to the Punjab Plains. For this reason it is ethnologically more closely related to Central Asia than to India. Until 1922 no structural remains in India could be assigned with certainty to a period earlier than the 3rd century B.C.; later excavations at Harappa and Mohenjo-Daro (Mohenjo-daro) unearthed the remains of a civilization 5,000 years old bearing a general resemblance to that of Elam and Mesopotamia (see INDUS CIVILIZATION).

The first migration of which there is any evidence, however, is that of the Indo-European (Aryan) peoples who entered the Punjab in prehistoric times. Centuries later, within historical times, successive waves of other invaders swept through the frontier passes; and all these migrations and invasions added to the heterogeneity of the population. (For languages see PANJABI LANGUAGE; LAHNDĀ LANGUAGE.)

The exact limits of the Achaemenian empire of Darius I cannot be determined, but it included the Indus Valley and probably parts of the Punjab (see PERSIAN HISTORY). The earliest date known for certain in Indian history is Alexander the Great's invasion of the Punjab in 326 B.C. (see ALEXANDER III [The Great]). His invasion was merely a large-scale raid and his death in 323 prevented consolidation of his power in the Punjab and the Indus Valley. The history of northern India proves that the mountain barrier of the northwestern frontier seldom formed a political boundary, for the kingdoms of the Persians, Mauryas, Greco-Bactrians, Sakas, Parthians, Kushans, and Hephthalites extended from Afghanistan to the Punjab Plains.

The first Muslims to penetrate into northern India were the Arabs who, in A.D. 712, extended their power to the Lower Punjab; but the Muslim conquest of the Punjab was the work of Mahmud of Ghazni (q.v., 971–1030). The Punjab remained in Ghaznevid hands until Mahmud's descendants were expelled by Mohammed of Ghor in 1186. It formed part of the sultanate of Delhi from 1206 until Babur's victory at Panipat in 1526 paved the way for the foundation of the Mogul Empire, of which the Punjab remained a part until disintegration set in during the first half of the 18th century.

The religious intolerance of the Mogul emperors after the death of Akbar in 1605 led to the growth of Sikh political power in the Punjab and transformed a religious sect, founded by Guru Nanak in the second half of the 15th century, into a military organization animated with undying hatred toward Muslims. The weakness of the emperors who succeeded Aurangzeb facilitated the growth of Maratha power. By 1758 Maratha armies had overrun almost the whole of northern India as far as Peshawar. They were gradually driven southward by the Afghans under Ahmad Shah Durrani to Panipat, where they were routed with enormous losses on Jan. 14, 1761. After the death of Ahmad Shah the various Sikh groups or *misl*s began to consolidate their power in the Punjab. The most important of these *misl*s were the Bhangis of Gujrat, Sialkot, Lahore, and Amritsar; the Ahluwalias of Kapurthala, Jullundur, and Hoshiarpur; and the Kanahyas of Gurdaspur.

From 1790 onward, Ranjit Singh, the head of the Sukarchakia *misl*, rose to prominence as leader of the Sikh resistance to the Afghan ruler Zaman Shah. His attempt to establish his authority over his coreligionists, the cis-Sutlejian Sikhs, brought him into contact with the British, and an agreement was formed in 1809 by which the Sikh ruler accepted the Sutlej as his frontier. From that date his power increased rapidly. Between 1813

and 1821 he annexed Attock, Kashmir, Dera Ghazi Khan, and Dera Ismail Khan.

After the death of Ranjit Singh in 1839 the Punjab became the scene of widespread lawlessness, and power passed to the army of the Sikh Khalsa organization. Suspecting the British of contemplating annexation and eager for war, the Sikhs in 1845 invaded British territory but were defeated in desperate struggles at Mudki (Moodkee), Ferozeshah, Aliwal, and Sobraon. The terms of the treaty of 1846 did not prove acceptable to the Sikhs, and war again broke out in 1848. After the battles of Chillianwala and Gujrat the Punjab was annexed to British India on April 2, 1849. (See also SIKH WARS.)

The annexation of the Punjab brought the government of India into closer contact with the Pathan tribes of the northwestern frontier. The tribes remained under the control of the Punjab government until the creation of the North-West Frontier Province in 1901.

After World War I communal relations in the province were embittered, but far more serious than communal strife were the political disturbances culminating in the Jallianwalla Bagh incident of 1919. (For the Punjab Rebellion of 1919 see INDIA-PAKISTAN, SUBCONTINENT OF: History.)

In 1921 the Punjab was raised to the status of a governor's province. From 1922 until the passing of the Sikh Shrines Act, 1925, the peace was disturbed by the Akali Sikhs who wished to devote the revenues of certain shrines and temples to the spiritual benefit of the Sikh community. Throughout the inter-war period the Punjab passed through the same phase of political ferment as the rest of India, with a gradual transfer of power from British hands. It became an autonomous province in 1937. With the partition of the Punjab between India and Pakistan (1947) the boundary was fixed roughly along the line of the Sutlej up to beyond Ferozepur and then due north between Lahore and Amritsar to the boundary of Jammu and Kashmir along the line of the Ravi.

The immediate result was an outbreak of violence with much loss of life followed by a great mass movement of population. Partition also led to a dispute between the two countries over the division of the waters of the Punjab rivers (see PAKISTAN: History). The western section of the Punjab was a province of Pakistan until 1955 and was then merged for administrative purposes with West Pakistan. For the history of the eastern sector see PUNJAB (India).

(C. C. D.)

PUNJAB (Pakistan).—This area of West Pakistan is bounded on the north by the outer edge of the Himalayan foothills, northwest by the Northwest Frontier region, west by Baluchistan, and south and southeast by Sind and the Indian state of Rajasthan. The boundary with India to the east follows the Ujh and Ravi rivers from the north to a point about 14 mi. (22 km.) NE of Lahore and then cuts across the Bari Doab to the Sutlej about 12 mi. (19 km.) NE of Ferozepur; thereafter it follows the Sutlej. At the extreme south a small area on the east bank of the Sutlej secures the control of the Suleaimanke headworks to Pakistan.

The region is mainly an alluvial plain with an extreme climate and consists of the Bari, Rechna, Chaj or Jech, and Sind Sagar doabs or interfluves. The central parts of these doabs form uplands known as *bar* while the active floodplains are called *bet*. An extensive system of canals, including the Haveli system, Lower Jhelum, Lower Chenab, and the Thal project, has converted large areas, that were formerly desert wastes, into prosperous agricultural settlements. Wheat and cotton are the principal crops where rainfall or irrigation is sufficient; millets and gram are the chief crops in the drier western parts. The Salt Range to the northwest contains many minerals, especially salt and coal, and the Potwar Plateau across the Salt Range is rich in mineral oil. The principal city is Lahore, capital of West Pakistan. Other chief towns include Rawalpindi, Multan, Sialkot, Lyallpur, and Montgomery. See also PAKISTAN; LAHORE; MULTAN; RAWALPINDI; and references under "Punjab (region)" in the Index.

PUNJAB (India), a constituent state of the Republic of India created out of the eastern part of the former British-Indian province of the Punjab after the partition of the subcontinent between India and Pakistan in 1947. In 1956 it absorbed the Patiala and East Punjab States Union (PEPSU) which had been set up after partition. In the north the continuity of the territory is broken up by enclaves which constitute the Union territory of Himachal Pradesh. The name Punjab ("five rivers") is now a misnomer; only the Beas (Bias) is wholly in the state together with the upper Sutlej. (See also PUNJAB above.) The state has an area of 47,205 sq.mi. (122,261 sq.km.), and though one of the smaller states of India, is densely populated. Pop. (1961) 20,306,812. It is bordered on the west by West Pakistan, north by Jammu and Kashmir and a part of Himachal Pradesh, east by Uttar Pradesh, and south by Rajasthan. A new state capital was built at Chandigarh (q.v.).

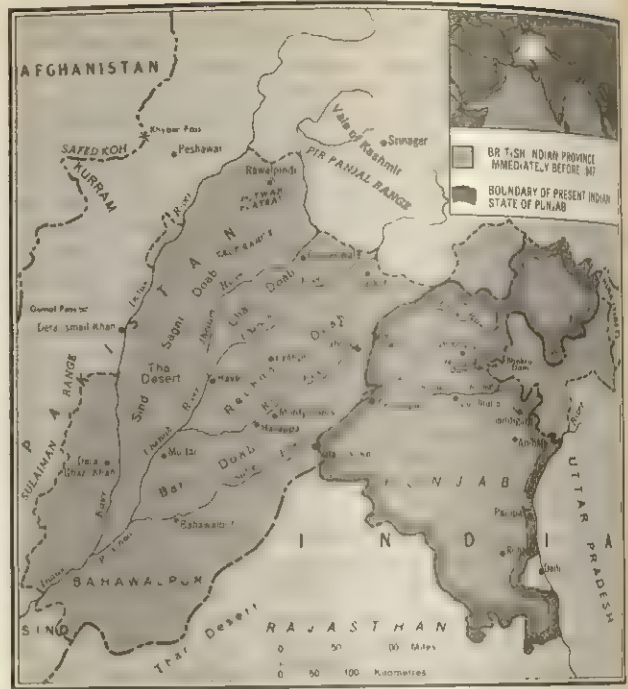

Physical Features.—Punjab State, as constituted, comprises three contrasted and unequal parts. In the north it shares with Himachal Pradesh a considerable section of the Himalayas. The boundary with Jammu and Kashmir has not been fully demarcated and there is a short section of frontier with Tibet. The Himalayan ranges trend northwest and southeast; melting snows and monsoon rains feed the headwaters of the Sutlej and Beas which flow in deep valleys. The great Bhakra and Nangal dams on the Sutlej hold up the water which feeds a great series of irrigation canals. The second and main section of the state is part of the great Indo-Gangetic plain of northern India, built up of a vast thickness of alluvium. It stretches westward from the Jumna (Yamuna) River, which is the boundary with Uttar Pradesh, across the Sutlej to embrace the doab or land between the Sutlej and Beas rivers (Bist-Jullundur Doab) and part of the Bari Doab between the Beas and Ravi. In the west the boundary with West Pakistan follows the Ravi River to a point above Lahore, then across the open plain southward to Ferozepur on the Sutlej after it has been joined by the Beas. In the south of the state a third region can be distinguished where ridges of old rock, the ultimate extension of the Aravalli Range, appear through the alluvium, and the surface drainage is irregular.

Because of their distance from the sea and the northerly situation, the plains of Punjab have a markedly continental climate with extremes of heat and cold. From October to March is the cool season, with warm, sunny days and cold nights. Frosts are frequent in January, and from January to March there is a small but useful cyclonic rainfall. From March onward there is a rapid rise in temperature; the atmosphere is dry and afternoon temperatures may reach 52° C (120° F). The rains break toward the end of June and some lowering of temperature results, but amounts of rain are small. The maximum total is reached in the outer ranges of the Himalayas (about 50 in. [1,270 mm.]), but on the plains there is only enough for a precarious harvest of millets and other dry-zone crops, except where irrigation water is available.

Little natural vegetation remains—scrub on uncultivated land and the foothills. Shade trees have been encouraged near the canals; these help to break up the otherwise monotonous sweep of the plains and to mitigate the effects of dust storms.

(L. D. S.)

History.—After the partition in 1947 the resettlement of refugees presented a grave problem: thousands of acres were unirrigated, schools remained closed, communications were disrupted, and there was constant friction along the new frontier. A serious water-supply wrangle and other disputes with Pakistan resulted from the Radcliffe boundary award which, being based inevitably on the preponderance of Hindus or Muslims in the areas concerned, disrupted such unitary services as canal irrigation, electric power transmission, and railways. In May 1948 India decided as a temporary measure to continue the supply of water from its

EXTENT OF PUNJAB AREAS OF INDIA AND PAKISTAN

side of the boundary to prevent famine in Western Punjab and Bahawalpur. It was not until February 1963 that the Bhakra Dam on the Sutlej River was completed. (For the Punjab river dispute see PAKISTAN: History.) In 1955 the Sikhs, led by Master Tara Singh, president of the Akali Dal, began to agitate for a Punjabi-speaking state. Tara Singh's activities led to his arrest in May 1960, but in order to promote a peaceful solution he and 6,500 Akali prisoners were released in January 1961. The failure to reach a settlement led Tara Singh in August to begin a fast unto death, which ended when a commission was appointed to inquire into Sikh grievances. The breakdown of negotiations produced fresh agitation, interrupted temporarily because of the Chinese attack in the autumn of 1962. In March 1966 the Congress Party suddenly announced that a separate Punjabi-speaking state would be created in Punjab. Riots followed between Sikhs and Hindus, the latter fearing a Sikh majority in any such state. (C. C. D.)

Population, Administration, and Social Conditions.—The population of Punjab at the 1961 census was 20,306,812, an increase of more than 25% since 1951 when it was 16,134,890. (See INDIA: The People; Population.)

The chief cities and towns with their populations (1961 census) are: Amritsar (384,287); Ludhiana (244,032); Jullundur (205,030); Patiala (125,234); Rohtak (88,193); Ambala (76,204); Karnal (72,109); Panipat (67,026); Hissar (60,222); Bhiwani (58,194); Bhatinda (52,253); Yamunanagar (51,700); Batala (51,300); Hoshiarpur (50,739). The state is bilingual and both Hindi in Devnagiri (Devanagari) script and Punjabi in Gurmukhi script are official languages. For administrative convenience the state has been divided into Hindi-speaking and Punjabi-speaking regions. Two regional committees consisting of the legislators and ministers belonging to the respective region tender advice to the government on certain specified questions. The chief minister is not a member of either committee. In case of conflicting opinions between the regional committees the governor's decision is final and binding.

There are 19 districts in the state. The Hindi-speaking region consists of the districts of Kangra; Lahaul and Spiti (formerly included in Kangra District); Simla; Karnal; Rohtak; Gurgaon; Hissar; Mohindergarh (Mahendragarh); Ambala (excluding the Rupar and Chandigarh assembly constituencies); and Jind and Narwana tehsils (administrative subdivisions) of Sangrur District. The Punjabi-speaking region consists of Gurdaspur; Amritsar; Bhatinda; Jullundur; Hoshiarpur; Ferozepur; Ludhiana; Kapur-

thala; Rupar and Chandigarh assembly constituencies of Ambala District; Patiala; and Sangrur (excluding Jind and Narwana tehsils). The Chandigarh capital project does not belong to either of the two regions, and pending constituency status, it was represented in the Punjabi Regional Committee.

The 1961 census recorded about 33% of the male and 14% of the female population as literate. Education is free up to seventh class in all institutions throughout the state, up to eighth class in some districts, and up to ninth class in flood-affected areas; it is compulsory for children aged 6 to 11 in more than 5,000 towns and villages. There are more than 15,000 educational institutions including three universities (Panjab in Chandigarh, Kurukshetra, and Punjabi in Patiala).

Under the government's health program which aims at providing medical relief for every village within a radius of five miles, health centres have been established in rural areas which offer institutional, domiciliary, maternity, child welfare, and school health services. Besides many hospitals and dispensaries, medical care is provided through panel doctors to factory workers and their families in the industrial centres under the employees' state insurance scheme which covers the risks of sickness, maternity, and employment injury. Welfare of tribal and other backward classes is provided through scholarships, subsidies for the construction of houses, community centres, technical education, and loans to assist establishment in trades. Welfare centres offer recreational and educational facilities to industrial workers. The state social welfare board provides state homes and district shelters for rescued women and men discharged from noncorrectional institutions, craft-training centres for women, and recreation centres for children. (S. CH.; S. B. L. N.)

The Economy.—Apart from the sparsely populated and partly forested Himalayas the whole of Punjab is an agricultural area. So long as the farmers relied on rainfall supplemented by a little irrigation from shallow wells only dry-zone crops—mainly millet—were possible and much fodder had to be grown to keep cattle alive. Good crops were possible only in years of ample rainfall. Irrigation canals were gradually developed during the British period. Main canal systems include the Western Jumna Canal—an old system repeatedly improved—drawing water from a point where the river leaves the Himalayas; the Sirhind Canal tapping the Sutlej; the Upper Bari Doab Canal leaving the Ravi near Madhopur. Other great systems lie in what is now Pakistan. On the Sutlej the Ferozepur Dam is in India, but much of the land it formerly irrigated is in West Pakistan. Irrigation permitted a great expansion in production of wheat, barley, and oilseeds with some rice and maize (corn) but especially (as a cash crop) of fine-quality cotton (Punjab-American), fodder, and some sugarcane. The state is one of the largest producers of wheat and grain in India; its annual cotton production amounts to one-fifth of the country's output. Stock raising is also important; the government farm at Hissar breeds the dual-purpose (draft and milk) Hariana cattle, which are among the best breeds in India. Since partition India has pushed ahead with river works, notably the Bhakra-Nangal dam system on the Sutlej, the largest multipurpose project in Asia, designed to irrigate 3,600,000 ac. (1,500,000 ha.). The Nangal headworks were completed in 1954. Progress has been made in developing the southern part of the state, but no major source of water exists there. There are no valuable mineral sources and hardly any coal. Forest resources are inadequate and concentrated in the Himalayan tract where exploitation is difficult.

The industrial growth of Punjab dates mainly from the early 1950s. Large-scale industries are the manufacture of cotton and woolen textiles, hosiery, sugar, cement, paper, and bicycles. Others include manufacture of agricultural implements, diesel engines, industrial machinery, and reolling of ferrous materials.

The state is served by the Northern Railway with headquarters at Delhi, where it is connected with the other lines of the Indian railway system. A section of the line runs north and northwest through Panipat, Ludhiana, and Amritsar and links up with the Pakistan Western Railway of West Pakistan. Chandigarh and Amritsar are linked by air with Delhi.

With partition the former capital, Lahore, went to Pakistan, so

India seized the opportunity of designing and building a new state capital at Chandigarh, on the rail and road route to the old hot-weather capital of India (Simla) and situated on ground high enough to escape the worst heat of summer. It was inaugurated in 1953 and is also the site of Panjab University.

The main towns of Punjab include Amritsar (*q.v.*), sacred city of the Sikhs; Ludhiana (*q.v.*), with cotton mills; Ambala (*q.v.*), a modern town of British origin; and Patiala, serving the expanding development in the south. Punjab is influenced by the very rapid growth of Delhi on its eastern margin. (L. D. S.)

PUNO, a southern sierra department of Peru, bounded north by Madre de Dios, west by Cuzco, Arequipa and Moquegua, south by Tacna and east by Bolivia. Pop. (1961) 687,077. Area 26,018 sq.mi. (67,387 sq.km.). The northern portion of the department was removed in 1912 to form a section of the department of Madre de Dios. Puno includes most of the shore of Lake Titicaca, the high plateau on which the lake stands and the mountains surrounding it on the north, east and west. Vilcanota Knot, on the border of Puno and Cuzco, constitutes the watershed dividing the enclosed lacustrine basin of Titicaca from the Amazon basin. The department is the source of the headwaters of the Amazon, notably the Tambopata and Inambari, affluents of the Madre de Dios.

Crops cultivated in the region are limited to those that mature in a cold climate: chiefly potatoes, barley, and other hardy cereals. Cattle and sheep are bred there; wool, both from sheep and alpaca, is exported. The department contains one of the most important auriferous regions of the world. In addition to silver and gold which have been worked extensively, coal, salt, copper, antimony, cinnabar, arsenic, quicksilver, tin, marble, zinc, cobalt, and petroleum are found. The manufacture of pottery and woolen textiles are also important industries.

The city of Puno, pop. (1961) 25,145, capital of the department and province of Puno, lies at an elevation of more than 12,600 ft. (3,840 m.) above sea level, on the northwest shore of Lake Titicaca: it is the seat of a bishopric and a superior court. Puno is connected by the Southern railway with both Cuzco and the Pacific port of Mollendo and with La Paz, Bolivia, by steamer across Titicaca and railway. Motor roads connect with Cuzco, Arequipa and Guacui and northeastward to Sandia and Ollachea. Puno is 171 mi. (275 km.) from La Paz, 218 mi. (350 km.) from Arequipa and 820 mi. (1,320 km.) from Lima. (J. L. Tr.)

PUNTA ARENAS, with the exception of Ushuaia, Tierra del Fuego, the southernmost city of the world, capital of Magallanes province and department, Chile. Pop. (1960) 49,504. The city, located on the Strait of Magellan, was founded in 1849 by Col. José de los Santos Mardones. Punta Arenas' role as a port-of-call and coaling station waned after the opening of the Panama Canal and fuel oil became significant in maritime movement; nevertheless, a flourishing export trade in wool and mutton, primarily with the British Isles, continues. Punta Arenas supports slaughterhouses, tallow works and wool exporting houses. The administrative and supply activities of the national petroleum company that operates in oil fields on Tierra del Fuego, the recreation requirements of its employees, the attractions of the free port to Chilean consumers and the maintenance of naval, air, and army garrisons are contributing factors to the city's growth in the 20th century. Frame and corrugated metal construction predominates among the city's buildings. Surface and air communication with the north and Tierra del Fuego is good. Some lignite and placer gold are mined nearby. From 1927 to 1937 the city was called Magallanes. Punta Arenas means "sandy point." (J. T.)

PUNTA DEL ESTE, a beach resort on the Atlantic coast of Uruguay, about 100 mi. (161 km.) E of Montevideo by road. Its location at the tip of a peninsula provides an ocean surf beach (*playa brava*) on the eastern side and a protected beach (*playa mansa*) on the western side. Its delightfully breezy summers (mean temperature of warmest month, 72° F [22° C]) originally attracted families from Buenos Aires and Montevideo, who built the beach-side chalets that give the resort its distinctive charm. In recent years new hotels, casinos, and the Cantegril Country Club, scene of international film festivals, have made Punta del Este a leading playground of South America. The resort achieved

international prominence as the locale of the 1961 meeting of the Inter-American Economic and Social Council, which proclaimed the Alliance for Progress, and of the 1962 Inter-American Foreign Ministers Conference, which suspended Cuba from membership in the Organization of American States. (E. M. V.)

PUNTARENAS or **PUNTA ARENAS** ("sandy point"), a seaport on the Gulf of Nicoya on the Pacific coast of Costa Rica. Pop. (1963) 19,582. In colonial times the city's chief function was to link Costa Rican commerce with Panama and South America. A royal order of 1814 brought the first attempt to improve the harbour facilities: a cart road from San José was opened in the 1840s. Most Costa Rican coffee went to Europe around Cape Horn, and Puntarenas was the shipping centre. Now connected with San José by the Pacific railway, it is an increasingly important port for exporting bananas as well as coffee. There is a considerable coastal trade in rice, corn and beans. Canning and freezing fish and ship repairing are relatively new industries in Puntarenas. Most imports to Costa Rica from the west coast of the U.S. pass through this city. It is the capital of Puntarenas province (area 4,247 sq.mi. [11,000 sq.km.]; pop. [1963] 156,508), a long narrow district that skirts the Pacific to the Republic of Panama. The province was the fastest growing in Costa Rica by the 1960s. Much of this was due to greatly increased activity in the banana industry as new areas opened on the Pacific coast. (T. L. K.)

PUPIENUS MAXIMUS, MARCUS CLODIUS: see **MAXIMUS.**

PUPIN, MICHAEL IDVORSKY (1858–1935), U.S. physicist, inventor of devices that are basic in wire communication over long distances (as in telephone and telegraph systems), was born in Idvor, Banat, Hung. (now in Yugoslavia), Oct. 4, 1858. He went to the U.S. in 1874, graduating from Columbia University, 1883. The first to hold the John Tyndall fellowship (1886–88), he later studied physics and mathematics at Cambridge University and under H. von Helmholtz at the University of Berlin (Ph.D., 1889). He was instructor in mathematical physics at Columbia, 1890; and was appointed adjunct professor of mechanics, 1892, becoming professor of electromechanics there in 1901 and later director of the Phoenix Research Laboratories. By means of inductance coils placed at predetermined intervals of the transmitting wire, he greatly extended the range of long-distance telephony, particularly over telephone cables. The patent for this invention was acquired in 1901 by the Bell Telephone Company and by German telephone interests. He made several other inventions in electrical wave propagation, electrical resonance and multiplex telegraphy. He discovered secondary X-ray radiation in 1896 and invented in the same year means for short exposure X-ray photography by the interposition of a fluorescent screen. He wrote *From Immigrant to Inventor* (1923). He died in New York City, March 12, 1935.

See D. Markey, *Explorer of Sound: Michael Pupin* (1964).

PUPPETRY is, broadly, the conveying of a concept to an audience through the manipulation (*i.e.*, movement by hand, directly or indirectly) of inanimate objects. A limited but more common understanding of the term has reference to small models of the human form which are used to present plays. (The word puppet is derived from the Latin *pupa*, is cognate to the French *poupée*, and is the modern variant of the Middle English word *poppet*—each of which can mean "doll.") Although the limited definition is satisfactory for most forms of puppetry it does not recognize the gloved hands of Yves Joly of France or the 10-to-30-ft. puppets of Remo Bufano of the United States. These variations in size, material, and form suggest that almost anything can be used for puppetry. It is the way the objects are manipulated (usually in a special setting, and commonly with the addition of voices) that makes them lifelike and causes the audience to react.

KINDS OF PUPPETS

In their more conventional forms, puppets are operated from above, below, or behind with rods or strings, or by direct hand contact. They are either three-dimensional or two-dimensional

and are seen with light directly on them or as shadows. It is these characteristics which divide puppets into various categories.

Hand Puppets.—Hand puppets are the simplest to make and operate. In their basic form they consist of a simple covering for the hand of the operator; two arms and a head. Commonly the index finger extends into the neck and head of the puppet, the thumb into one arm, and the second finger into the other arm. Sometimes the hand covering has accessories; *e.g.*, a ball to represent the head or a handkerchief to provide the body. The covering material may be any fabric, although one which holds the form of the puppet's body without collapsing is usually preferable. The fabric pattern should enhance, not detract from, body form.

Padding may be added to the body and extensions made on the neck and arms to increase the size of the puppet; however, any such gain in size is ultimately limited by the size of the puppeteer's hand. Another variation may be achieved by sewing on arms which appear to be bent, but with the hands positioned at the normal extension of the fingers of the operator; this heightens the illusion of the human form without sacrifice of control such as occurs when cumbersome length is added to the puppet's extremities. Some hand puppeteers add stuffed legs to the stuffed body of the male puppet; the puppet must then be equipped with a sleeve extending below the level of the stage front. These variations, like all features of puppet design, are a matter of the puppeteer's individual opinion as to what is needed for successful performance.

The head of the puppet, as well as the hands, can be carved from wood or a foam plastic such as Styrofoam, cast in plastic wood, fibreglass, Celastic, or papier-mâché, modeled from papier-mâché, clay, or a plastic or sewn from cloth such as felt, muslin, or jersey. The ingenuity of the designer makes almost any material possible. Even the end of a sock may be stuffed, tied off, and painted or embroidered to represent a head. The basic requirements for heads and hands are that they be relatively light and resist damage from rough handling.

While some hand puppets have been constructed with bodily proportions resembling those of human beings, the heads usually are considerably outsize compared with the body and the arms are quite foreshortened. Although a real person reacts with his whole body, in a hand puppet the head necessarily becomes the major indicator and, consequently, is exaggerated. Certain elements—nose, mouth, eyes, or hair—are often abstracted and heightened. Visibility is also a factor in the matter of exaggeration or abstraction. Sometimes the puppeteer may install a movable mouth, eyes that close, or ears that wiggle. While adding the interest of action and close-up expression, the mechanics and synchronization of these elements may also prove distracting and complicating.

Many puppeteers consider the hand puppet to be the ideal form, since the most delicate control can be maintained directly through the hands and fingers. The puppet is exceedingly responsive, unencumbered by levers or strings, it moves either rapidly or slowly, depending on the requirements of the performance. The Punch-and-Judy show, with its swift strikes and slow "sneaking up," suggests the extremes of operation. In addition, the hand puppet can pick up and handle properties, since it has the strength of the hand of the operator. In other puppets, where the puppeteer is at a mechanical remove, such operations are sometimes clumsy, if not impossible.

There are, however, limitations other than the size factor (see above). One is the requirement that the hand puppet must almost always have its lower end concealed behind the lower edge of the stage. Another is the limitation on things which can be done on the floor, since, with the exception of the front ledge of the stage, or playboard, there is actually no floor. The essential simplicity of hand puppetry, however, makes it one of the most popular forms of the art.

String Puppets (Marionettes).—Just as hand puppets are usually operated from below, string puppets, or marionettes, are usually operated from above. Thus, while the hand puppet has a space (normally concealed) below it to house the operator the string puppet needs a space above the stage.

It is usually thought that a marionette is one thing and a puppet another. Actually, the names are often used interchangeably. In current usage the word marionette indicates a string-operated figure belonging to a subclass of puppets. The origin of the term is just as cloudy as are other aspects of the beginnings of this art. A commonly accepted explanation is that such figures were used in Nativity scenes in churches, the one of Mary being called *maryonete* (Middle French, "little Mary"). Another explanation connects the term with the Italian *morio*, which means "buffoon" or "fool."

While the hand puppet usually uses the operator's hand for the body, the body of the string puppet must be constructed. Customarily it is made of wood with cloth, leather, or pin hinges; but, as with the hand puppet, the materials are limited only by the designer's imagination. Eric Bramall of Wales, for instance, performed a string-puppet ballet with puppets that were chiffon handkerchiefs tied at the corner with a string.

Soft woods such as pine or cedar, any of a number of plastics, or stuffed fabric can be used for making the body of the string puppet. It should be noted that the string puppet's movements are the result of the string acting against the force of gravity. If the materials are either too light or too heavy the resultant action will appear unnatural, at least in the case of puppets designed to represent human beings. As is the case with most constructions which are less than life-size, compensation is made in the costuming to assure freedom of motion; thus a jersey cloth might be substituted for a heavy damask or a cotton batiste for a broadcloth. Cut of the fabric and means of mounting also affect mobility.

The head, hands, and feet are carved or cast much as for the hand puppet. Although somewhat smaller in proportion to the body than those of the hand puppet, they are nevertheless usually exaggerated.

Stringing the puppet can be as simple or as complex as the designer wishes. One string from the top of the head suffices to keep the puppet upright and allows rather aimless movement. Normal stringing would include one string for each side of the head, one on each shoulder for major support, one for each arm or hand, one for each leg, and one at the middle of the back. Elaborations include strings at the back of the feet, a string between the hands so they may be brought together, double stringing of the lower arm, a string to the centre front, double stringing of the legs, and auxiliary strings for the head if movements of the eyes and mouth are involved. These are for figures that resemble people; other forms require special variations. The string used for puppet manipulation is most often a black fishline, although fine wire, clear nylon filament, or other stranding may be employed. The ultimate intent, as in all of puppetry, is to minimize the intrusion of the operator.

The strings go to an arrangement of sticks, called the controller or control, which is held above the puppet. Its design varies with the number of strings involved, the complexity of action, and the personal preferences of the designer or operator. In the United States a horizontal ("airplane") control is most common; a vertical control is widely used in England. Trick string puppets, which became popular in the 19th century, had elaborate controls which could be moved apart and might require two or three operators. Most marionette controls are in two sections, one being a separable control for the leg strings.

The puppeteer's freedom of action above the stage floor and the almost unlimited size and shape of marionettes are among the advantages of this form. The marionette can seem to defy gravity—which is helpful in creating an airy or supernatural effect. The string puppet can also have legs without a large support. On the other hand, quick and positive action is less easy to accomplish. In downward and horizontal action the string puppet has only its own weight or momentum. While the hand puppet must be operated without a floor, the string puppet must be operated without a ceiling—which makes passing through arches somewhat difficult. Although the string puppet most often appears on a stage above which the operator is concealed, it is not uncommon to see the operator (e.g., a nightclub entertainer) in full view and using very short strings; in these instances he is dressed in subdued colours

and depends on the attention-getting power of the puppet to make him "invisible."

Rod Puppets.—Puppets supported on rods are, in effect, marionettes operated from below. As Marjorie Batchelder McPharlin has pointed out, rod puppets permit a degree of control unmatched in other puppets, where the operator is farther removed. Through extension of the rods, larger puppets are possible than is the case with hand puppets, but certain problems of control can develop in the more elaborate versions.

As in hand puppetry the operating space is located below the stage. The bottom of the stage may be completely open, which allows free movement in three dimensions; or it may be constructed with slots, in which case the puppet is equipped with a small disk at its base, which allows the puppet to be left in position without dropping through the slot. On a slotted stage there usually are points where the puppets can be removed from the track, as well as a slot running from front to back down the centre of the stage. Where the audience seating is elevated or numbers of puppets are to remain stationary, this type of construction is almost essential.

Materials for making three-dimensional rod puppets are much the same as for other puppets with the exception of the central supporting member, which is a rod of wood or steel. The rod extends below the performing level and provides a grip for the operator. In southeastern Asia, China, India, and the eastern Mediterranean countries rod puppets are often found in two-dimensional or shadow form. (See *SHADOW PLAY*.) Here the materials may be animal hides which have been elaborately cut and coloured and have supporting members of horn or bamboo. While the problems of production may vary slightly, the movement and operation remains much the same.

With the string puppet, overall support is maintained with the shoulder strings; for the rod puppet this is provided by the central rod. For more elaborate control additional rods are used; e.g., one for each hand and one for the head. Still greater control can be achieved through leg rods and a spring joint with a control rod to allow the puppet to bend at the waist.

A minor variant of the rod puppet is the simple jointed puppet with a rod extending from its back at right angles to the puppet's perpendicular. This puppet can be shown as a shadow or on a stage with the operator in plain view of the audience. The rod merely avoids visual distraction by removing the hand of the operator from the immediate proximity of the puppet.

The so-called paper theatres, popular primarily in England and continental Europe during the 19th and early 20th centuries, utilized a cardboard strip or a rod extending out from the side of the stage. The characters, made of cardboard, could be moved back and forth to act out scenes from plays. The action was, obviously, limited.

Composite Types.—While rod puppets are often found in the "pure" form, they are most often combined with other types to achieve greater flexibility or sensitivity. Or perhaps the other forms adopt the rod for the same reason. This results in hand-and-rod puppets, string-and-rod puppets, or a hand-rod-string combination. For example, to obtain closer control of balance of the rod puppet the central control is shortened so as to place the hand of the operator up inside the body, with fingers extending into the arms. Or one hand grips the central control within the body and the arms are manipulated by rods. In some instances, such as the Japanese *buraku*, all the rods are shortened and the operator manipulates the rods and strings inside the puppet while he stands in full view of the audience. The 10-ft. puppets of Remo Bufano for the 1932 production of *Oedipus* in New York City were operated with rods supporting the central weight from below while other operators stood above the stage on a scaffold and manipulated the heads and arms by means of strings. The puppets of Liège, France, utilize a single rod from the top of the head; essentially the same form is found in the puppets of Sicily, where another rod is added for the sword arm and a string or rope controls the shield arm. The puppets of the Kungsholm opera theatre in Chicago, as well as those of Richard Teschner of Germany, employ the central control, rods for the arms, and

strings inside the puppet for leg and head movement as well as for bending to the front or back. George Latshaw's giant puppets for *Billy the Kid*, performed with the Detroit Symphony in 1959, required one to three persons to control the body, arms, and legs with both internal and external rods; the operators were in full view of the audience.

ILLUSION AND ARTISTRY

Puppets inhabit a wonderful world of their own. Once the performance starts, just as in the theatre of human performers the audience is asked to suspend disbelief. Within this framework the artist performs through the puppet. Normal concepts of space and shape appear to be altered as concentration is fixed upon the puppet. The dancing finger puppets of Herb Scheffel, where the index and middle fingers form the legs, seemingly increased in size even though they were nothing but pieces of fabric and wood fastened to a man's hand. Eighteen-inch marionettes of the Salzburg Marionette Theatre become full-sized performers on an operatic stage. Abstract shapes forming and reforming themselves, animals, flowers, trees, rocks, buildings—all can come to life in a puppet show. The human form can be distorted to suggest personality characteristics in a way that is impossible on the live stage. Music, colour, and special effects can be utilized to inspire, instruct, or amuse. The flexibility of the puppet theatre is almost without limit. The breadth of its possibilities is, however, often ignored and the puppets used only to present things in miniature which could more successfully and easily be done full-scale.

PUPPETRY AROUND THE WORLD

The origins of puppetry, like the beginnings of most of the arts, are prehistoric and are confused in a myriad of conflicting patterns and explanations. There is general agreement among scholars, however, that puppetry, although its origins do not lie exclusively in the Orient, became a highly sophisticated art there at an early period and that the Orient was a source of ideas and techniques for a good deal of the puppetry of the West. The general East-to-West trend discernible in the history of puppetry provides, therefore, the rationale of this section under the headings *The Orient*; *Europe*; and *The United States*.

THE ORIENT

The earliest recorded material on puppetry in the East is contemporary with that of the West. Although some elements were slow to evolve, many features are today the same as they were three or four hundred years ago.

Japan.—In Japan as in Europe (*see below*) the drama was closely allied with religion, and dolls were used to represent supernatural forces. Elements of both the *nô* drama and the kabuki theatre (*qq.v.*) are found in the puppet theatre, which reached its zenith in the 17th century in the work of Chikamatsu Monzaemon (*q.v.*) and others and maintained a high technical level for the next two hundred years.

The *bunraku* puppet of Japan (named for the puppetmaster Vemura Bunrakuken [1737–1810]) is approximately two-thirds life-size, with head, hands, and feet somewhat smaller in scale. It is operated by a chief puppeteer who inserts his left hand into the back of the puppet and controls the head by means of a rod to which are attached auxiliary levers for the eyes, mouth, and eyebrows. The right hand of the chief operator controls the right arm of the puppet, which may also be articulated. A second puppeteer controls the left hand and stands somewhat back from the puppet. A third puppeteer operates the feet or, in the case of female puppets, the base of the costume. The stories may be either historical or domestic, but all are highly stylized. The performance takes place on a full-size stage complete with scenery. To the right of the stage are the reciters, who tell the story and speak the lines, and the *samisen* musicians who accompany the action. Besides the *bunraku* puppets, string puppets were also used in Japan.

China and Java.—A somewhat different form of puppetry developed in southeastern Asia (particularly Java) and China. The

beginnings may be traced before the 10th century; more specific references are found after the 16th century. The general form of puppetry is called *wayang*; its development falls into three basic categories: *wayang kulit*, a shadow puppet; *wayang klitik*, a shadow puppet with carved relief; and *wayang golek*, a three-dimensional puppet. The evolution of puppetry here seems to have been from the basic shadow puppet of the religious ceremonies to the three-dimensional puppet of the secular dramas. A further advance was transmutation into the dance, which mimics the movement patterns of the puppets and the angular limitations of their jointing.

The shadow puppets are cut from animal hide with horn supports. Elaborate configurations, cut into the hide, serve to define the character. The puppets vary in size from six or eight inches to four or five times that large. Principally, the arms are articulated with two rods for manipulation. Elaborately painted, the puppets perform for a male audience in front of a screen with a light shining on them; on the other side of the screen, women view the performance as a shadow play.

The *wayang klitik* puppets are also shadow puppets but they are of translucent material. Brilliantly coloured, they are often very complicated and are presented in the midst of elaborate scenery and properties. In China the shows do not have the religious connotations of the Javanese performances. Chinese puppets are also to be found in three-dimensional rod form as well as rod-and-string and hand-and-rod forms. As with all other puppets, their origins are lost in antiquity.

Bali and Turkey.—Somewhat akin to the Javanese puppets are the animal-skin shadow puppets of Bali and Turkey. In Bali the puppets often are more complex: strings are used and smaller portions of the puppets are articulated. These puppets also seem to exhibit more humour. The translucent Turkish puppets have the rod inserted at right angles to the puppet in a slot on the puppet's back. The puppet is pressed against the screen, and the light comes from behind the puppeteer. This eliminates the need for supporting pieces fastened to the puppet but poses some difficulties of operation.

India.—The shadow play is well known in India, and there are also string-puppet plays. In spite of the simplicity of their stringing, these puppets are elaborately costumed.

EUROPE

Mediterranean Origins.—Puppetry in the West apparently began in the Mediterranean region. Major evidence is supplied by archaeological remains, folk legends, cognate words, and documents.

Dolls from the Old and Middle Kingdom tombs of Egypt suggest action in both large and small figures, but the seeming articulations may have been a construction feature of figures that never moved. A mask of the dog-headed god Anubis with a movable jaw may be an example of one of the earliest manifestations of puppetry: the use of moving parts in idols to give them a heightened dramatic effect. Made by religious communities from the Greeks onward, figures of this kind were finally banned by the Church of England during the Reformation. Their clockwork brothers, however, remain on the towers of municipal buildings and in other secular settings to this day. (Automata are not considered to be puppets, since they move of themselves.)

From Etruscan tombs and Roman sites come doll-like images with rods protruding from their heads. While some of them are articulated, their use is much debated. There are remnants of Greek and Roman theatres that suggest the origins of the *com-media dell'arte* (16th to 18th centuries), from which may have come the style and, in part, the form of Punch (*see below*, "Com-media" Influence); but it is to be suspected that over a span of nearly two millennia there was not a single continuous line.

The writings of Herodotus, Plato, Aristotle, and Horace contain seeming references to the art of puppetry; whether there were actual performances is, however, debatable. Until the establishment of municipal records and their preservation, and of more accurate record-keeping of all sorts from the Renaissance forward, the rather ephemeral art of puppetry left little mark. By the very

nature of their construction, puppets soon deteriorated, and few permanent structures were built for their performances. While they may have influenced language, social patterns, and religion and did show up occasionally in pictures, puppets were not, apparently, considered worthy of lasting recognition.

Early Developments.—From an early date both live performers and puppets took part in the church's representations of religious stories. There are descriptions of angels ascending and miraculous happenings, in performances within the church edifice and on pageant wagons, which were accomplished with the aid of puppets. Dragons and lions were brought onstage in a very realistic fashion in sacred dramas—an early demonstration that puppetry is most successful when its themes are those which cannot be represented in actuality.

Christmas manger scenes (*crèches*) in 16th-century France and Italy made use of animated figures, and it was just a short step to other stories and more elaborate action. How much of the action was performed with machines and how much by human manipulation is uncertain; perhaps the human element was a well-kept secret, since the public has always been fascinated by mechanical contrivances and feels cheated if it is revealed that a human being performed some or all of the movements.

"Commedia" Influence.—By the middle of the 16th century the *commedia dell'arte* (*q.v.*) of Italy was flourishing and, seemingly, puppets were firmly mixed with it. The puppets outlasted the living actors, in the form of Pulcinella in Italy, Polichinelle in France, and Punch (*q.v.*) in England. Considerable controversy revolves about the genesis of these terms. Stock characters of the *commedia* also evolved into Kasperle in Germany and Petrouchka in Russia—each an underdog with a well-developed sense of defiance of authority. Guignol of France, which came along two centuries later, has a certain family resemblance.

National Traditions.—*Italy.*—The shadow theatre reached Italy by way of Turkey, and appearances are recorded in the 17th and 18th centuries on the continent and in England. There is some problem of identification here, for puppeteers preferred to keep their methods secret (as is true today).

In southern Italy and in Sicily there is a particular kind of puppet show which, though related to forms of puppetry farther north, in Belgium and France, developed a pattern all its own. Based upon the adventures of Charlemagne and Roland, these tales of Saracens and Christians delighted audiences well into the 20th century. Where these shows began is a matter of conjecture. The puppet versions date from the 11th century and were written down in the 15th century, but each performance is the creation of the puppeteer. Performed by puppets approximately four feet high and weighing 75 to 100 lb., the stories go on almost endlessly. Each evening's performance is liberally punctuated with fierce battles between opposing armies, heroes and monsters, or heroes and witches. Blood flows freely and, as each puppet is killed, the rods supporting him are thrown to the floor. A large supply of puppets is necessary since, once having died, it ill befits a puppet to show up again within that cycle. With changing of folkways these puppet shows are gradually disappearing after centuries of popularity. The remaining puppeteers perform in the evening after making their living at other tasks during the day.

Punch was long active in Italy under any number of names. Just as he varied from country to country, within Italy he was known as Pulcinella in Naples, Rugantino in Rome, Fagiolino in Bologna, Sandrone in Modena, Arlecchino in Venice, Meneghino in Milan, Gianduia in Turin, Varticchio in Palermo, and Gioppino in Bergamo.

France.—Jean Brioché (Giovanni Briocci), an Italian, firmly established puppetry in Paris and performed before the dauphin in 1669. He was followed by a man named LaGrille, who performed with puppets four feet high. At the end of the 17th century a battle between puppetry and live theatre took place in France, with the Opéra, the Comédie Française, and the Comédie-Italienne on one side and various puppet establishments on the other. (A similar rivalry arose in other countries.) Dominique Seraphin was busy with his theatre in Paris starting in 1776; he

used string figures at first but apparently introduced hand puppets later.

England.—In 1573 a letter from the Privy Council to the lord mayor of London authorized some Italians to perform their "motions" within the City. This term is commonly used interchangeably with puppets, and puppeteers were "motion men."

The first recorded performance of *Punch and Judy* on English soil was at Covent Garden in 1661. Prior to this time there were references, possibly to puppets, as in *A Midsummer Night's Dream*:

Helena: Fie, fie! you counterfeit, you puppet, you!
Hermia: Puppet! why, so: ay, that way goes the game.
Now I perceive that she hath made compare
Between our statutes. . .

Shakespeare's reference, as with others earlier, may have been to a doll rather than to figures operated on a stage. There is no doubt, however, about Congreve's reference 100 years later in *The Way of the World*, when Lady Wishfort observes:

Why dost thou not stir, puppet?
Thou wooden thing upon wires!

This uncomplimentary view of puppets (latterly given a political meaning) is all too common in English writings. It may have sprung from the running battle between the live stage and the puppet stage, which has been going on for hundreds of years in spite of the many elements they have in common and repeated borrowings from each other.

From the 17th century onward, many English sources tell of puppet shows as entertainment at fairs and in permanent establishments. For instance, one of the offerings of John Harris's booth at Bartholomew Fair in 1650 was *The Court of King Henry II, The Death of Fair Rosamond, with the merry humors of Punchinello and The Lancashire Witches*.

The name of Martin Powell dominates puppetry in 18th-century England. He performed in Covent Garden in London, at Bath, and elsewhere with considerable success. His puppets were operated with strings and wires by his assistants, while Powell himself, a short man with a decided paunch and hump who bore some resemblance to Punch, delivered a prologue and running commentary on the shows from a position in front of the stage. Among his shows on March 18, 1712 (new style; 1711, old style), was *The False Triumph, or The Destruction of Troy*, on other dates he presented *King Bladud, The Beauteous Sacrifice, Heroic Love, or The Death of Hero and Leander*, and *The Vices of the Age Displayed, or Poor Robin's Dream*. His performances were advertised regularly in *The Spectator* (no. 295-550). Other London puppeteers were John Harris, Jean Dumont, Mme de la Nash, and Charlotte Charke. Puppets were also to be seen at Norwich, Kent, and Canterbury. Hand as well as string puppets were used in 18th-century England. The programs varied: there were standard tales, tableaux, social commentary (usually somewhat disguised), and variety turns, with the last-named gaining in popularity toward the end of the century.

The most notable English puppeteer of the 19th century was Thomas Holden. His performances were frequent and elaborate, employing upward of a dozen persons and involving all sorts of trick puppets: singers that turned into balloons, stretching puppets, jugglers and stilt walkers, and seemingly single puppets that turned into many puppets. Throughout the century *Punch and Judy* shows were extremely popular.

Other European Countries.—Both Gluck and Haydn composed operas for the 18th-century puppet theatre of Germany and Austria. In the latter part of the 19th century Maurice Sand was active for more than a quarter of a century doing hand-puppet shows at Nohant, Switz.; in his Theatre des Amis his mother, the writer George Sand, spent much of her time in costuming his puppets.

Early puppetry in Czechoslovakia followed the traditional pattern of string and hand shows. Kaspárek, a Punchlike character presented by Matej Kopecký at the end of the 18th century, was followed by the puppets of Jan Lastovka which voiced the revolutionary sentiments of 1848. Political commentary continued with the puppets of Joseph Skupa in 1917. Annexation by Ger-

many in 1939 caused many puppeteers to leave the country, but Czechoslovakia still has a high ratio of puppet theatre to population.

20th-Century Revival.—By the beginning of the 20th century many European puppet shows were permanently settled in their own theatres, such as those of Munich and Cologne. During the first half of the century a number of persons gave puppetry a new artistic lease on life. Chief among them was Edward Gordon Craig (*q.v.*) of England, who in 1907 suggested that life-size puppets would constitute ideal actors. His use of puppets and interest in them led the puppet revival. Those who took part in Europe and Russia included Richard Teschner in Vienna, Paul Brann in Munich, Ivo Puhony in Baden-Baden, Nina Efimova in Moscow, and Gera Blattner in Paris. Among the performing groups remaining in the 1960s (some of which were started during the revival) were the Teatro Piccoli of Italy, Anton Aicher's Salzburg Marionettes, the Lalka Theatre of Warsaw, and the State Central Puppet Theatre of Sergei Obraztsov in Moscow. While many of the theatres and troupes on the continent were privately managed, there was a tremendous upsurge in puppetry financed by national governments, particularly in eastern Europe.

THE UNITED STATES

One of the earliest references to puppetry in what is now the United States was the following advertisement in the *Pennsylvania Gazette* of Dec. 30, 1742.

At the sign of the Coach and Horses, against the State House, in Chestnut Street, Philadelphia, every evening at seven a clock [sic] precisely, will be acted, in several scenes, viz. An agreeable comedy or tragedy, by changeable figures of two feet high.
A sight of the sea and ships.
A merry dialogue between Punch and Joan his wife.
With several other pleasing entertainments. The prices, two shillings, eighteen pence and sixpence.

Another picture of puppet entertainment is given in the following notice of Peter Gardiner's troupe from the Williamsburg, Va., *Gazette* of Nov. 19, 1769:

A curious set of figures, richly dressed, four feet high, they are to appear on the stage as if alive, and will perform a tragic performance called *Bateman and his Ghost*. Likewise a set of water works, representing the sea monsters sporting on the waves together with the taking of Havannah, with ships, forts and batteries, continually firing, until victory crowns the conquest; and a magnificent piece of machinery, called *Cupid's Paradise*, representing seventy odd pillars and columns, with the appearance of Neptune and Amphitrite, and music suitable thereto. The whole to conclude with a magnificent set of fireworks, such as Catherine wheels, Italian candles, sea fountains, and sunflowers with the appearance of the sun and moon in their full lustre.

Chinese shadow puppets appeared at the end of the 18th century. Other shadows came from France; *e.g.*, a production of *Don Quixote* in 1812.

If any form may be said to have dominated the American puppet scene in the 19th century it was the variety show with string puppets. This was not, however, to the exclusion of the "story" show. Among the companies active during this period were Alberto Lana's, Bragaldi's, and the Theatre Seraphin, as well as multitudes of *Punch and Judy* operators. The puppets were sometimes called *fantoccini* (Ital., "little puppets") to add a foreign lustre. The puppets of the United States remained primarily touring attractions until the end of the 19th century. The companies, such as Till's Royal Marionettes headed by John Till, the Middleton Marionettes of Harry and George Middleton, and the Deaves Marionettes of Walter and Harry Deaves, presented almost anything that would attract attention, performing for adults as well as children and appearing often in the variety shows latterly known as vaudeville.

Immigrants brought their national puppets with them to the U.S. The technique and stories of German puppetry showed up in Pennsylvania, New York, and the Midwest. The Paladins of Sicily were taken to Boston by Antonio Parisi of Messina; he later moved to New York City, where there were theatres performing the tales of Charlemagne. There were also theatres of this type in Chicago and San Francisco at the turn of the century; the last of these was the Mulberry Street theatre of

Agrippino Manteo in New York City. Greek shadow puppets, bearing a striking similarity to Turkish puppets, could also be seen in coffeehouses and restaurants.

The opening of the 20th century did not suggest anything startling for puppetry in the U.S. The advent of motion pictures was taking away much of the audience—a factor in the decline of puppetry in many countries throughout the world. However, a revival began at the Chicago Little Theatre at the start of World War I. This was closely followed by the first professional show of the English artist-illustrator Tony Sarg in New York City in 1917. (It was with the Sarg company that many puppeteers still active at midcentury received their training.) Sarg productions toured in the 1930s and, by presenting a show with high standards, established a pattern which American amateurs could follow to become the new professionals. He saw puppetry as an integral form of theatrical art. Remo Bufano, another of those who were active early in the revival of puppetry in the U.S., constructed puppets of all shapes and sizes. Among his experiments were the previously mentioned *Oedipus*; *Master Peter's Puppet Show*; and a 35-ft. figure for Billy Rose's *Jumbo* at the Hippodrome. With Grace Wilder he directed the Federal Theatre Project (*q.v.*) puppet theatre in New York City. In Cleveland, O., Helen Haiman Joseph began puppetry at the Playhouse in 1915. Her *Book of Marionettes*, published in 1920, provided a background against which other work could progress. The company she organized continued to present local productions and touring shows until 1942. Paul McPharlin started in puppetry while at Columbia University in the 1920s. He went to Evanston, Ill., and then to Detroit, Mich., where he established Puppetry Imprints, was instrumental in founding Puppeteers of America, and published *Puppetry*, a yearbook of happenings in the art throughout the world. His collection of books and puppets became the basis for the library and collection of the Detroit Institute of Arts. He wrote *The Puppet Theatre in America* (1949), the first major work on American puppetry. One of the later proponents of puppetry within this period was Marjorie Batchelder McPharlin (Mrs. Paul McPharlin), who wrote extensively about puppets, particularly rod puppets, and traveled throughout the world doing research and teaching.

Several producing companies were formed during the 1920s and 1930s and performed throughout the U.S. One was the Tatterman Marionettes of William Duncan and Edward Mabley, which started in Detroit, later moved to Ohio, and then went to New York. Another, originating near Detroit, was the University of Michigan Puppeteers started by Forman Brown, Harry Burnett, and Richard Brandon. This group toured the Midwest and then went to Yale University, where it acquired the name Yale Puppeteers. After more touring and film work it settled in 1941 at the Turnabout Theatre, Los Angeles, where the puppeteers and live actors performed alternately at opposite ends of the same theatre.

Rufus Rose and Bil Baird, two of the puppeteers with Tony Sarg, continued to be most active. Rose and his wife, Margo, were traditional touring puppeteers known especially for their productions of *Pinocchio* and *Treasure Island*. The Rose Marionettes made one of the early puppet films, *Jerry Pulls the Strings* (1938). For many years Rose was the manipulator in *Howdy Doody*, one of the early puppet successes on television. Bil Baird and his wife, Cora, were among the busiest puppeteers in the country. Active in commercial productions since the Chicago World's Fair (1933), the Bairds presented several full-length television shows, performed at the New York World's Fairs of 1939 and 1965, and made international tours to India and Russia. Others who took part in the U.S. revival of puppetry included Romain and Ellen Proctor of the Proctor Puppets; Pauline Benton of the Red Gate Shadow Players; Ralph Chessé, who produced a puppet version of O'Neill's *Emperor Jones*; Basil Milovosoff, who used both Russian folk puppets and experimental forms; Martin and Olga Stevens, with their *St. Joan* and *Macbeth*; Frank Paris, originator of *Howdy Doody*; and Paul Walton and Michael O'Rourke of the Olvera Street Puppet Theatre.

Several American museums have collections of puppets, the

most notable being that of the Detroit Institute of Arts; this institution also presents performances by touring puppeteers and has commissioned special productions. The city of New York maintains a large marionette theatre which tours schools and parks, and the Museum of the City of New York presents a regular program of puppet shows.

Except for some nightclub performers, the Kroffts' Les Poupées de Paris, and the Kungsholm theatre of Chicago started by Fredrik Chramer and carried on by William Fosse, puppetry in the U.S. in the 1960s was almost exclusively the province of children. This was in decided contrast with the historical background of puppetry and its practice elsewhere in the world. Puppets were also firmly settled in U.S. television, where they perhaps were seen by more people in a 20-year period than puppetry as a whole had attracted in the previous 2,000 years. Following a decade of work in and around Chicago, Burr Tillstrom and his puppet Kukla first appeared on a daily television show in 1947. In the years that followed, *Kukla, Fran and Ollie* achieved a national following. Other favourite TV puppet characters were Howdy Doody, those of Cosmo Allegretti on *Captain Kangaroo*, Hope and Maury Bunin's Foodini, and Shari Lewis's Lamb Chop and Charlie Horse—all appealing primarily to children. The Muppets of Jim Henson, to some extent Tillstrom's characters, and those of an occasional foreign or domestic guest represented the only puppets performing principally for adult viewers of U.S. television.

LATIN AMERICA

Latin-American puppetry dates from the Cortés expedition to Mexico where, in 1524, one of the personal servants did sleight-of-hand and worked puppets. Since the Spaniards were very fond of puppets in their native land it was inevitable that puppets should be brought to the New World. References are made to performances at Tezcuco, Mex., by Juan de Samora in 1569 and at Lima, Peru, in 1629. As in Europe, the carefree attitude of puppeteers in regard to the licensing laws led to censure as well as to the familiar feuds between live actors and puppets: in Lima in 1787 indignation over puppet performances during Lent resulted in the closing of the theatre.

Leonardo Rosete Aranda, who started performing in 1860 in Mexico, laid the groundwork for companies which were to use his name into the mid-20th century. His plays, done with string figures, centred on folk and religious themes. I. T. Orellana's plays "for children or puppets," published from 1880 on, suggest the folk nature of the puppet theatre of that period. More recently the hand puppeteer Mane Bernardo of Argentina and Roberto Lago with his federally assisted theatre in Mexico have explored new directions for puppetry in Latin America.

MODERN USES OF PUPPETRY

Aside from its entertainment value, puppetry in the mid-20th century was receiving attention as a tool of education and advertising. Puppets can be used to instruct in almost any subject, since they can be made in so many shapes and can portray both abstract and concrete situations. Thus they were used extensively in India to educate the people in such matters as family planning, modern medicine, sanitation, and agriculture. A similar program in Mexico spread health information and improved literacy. In the U.S., puppets were used to promote dental hygiene and in schools and mental institutions to act out problems and find solutions. This also involved, in a therapeutic way, the manual skills needed to construct and present a puppet show. An introduction to puppetry was included in the curricula of many teacher-training colleges. At the University of California at Los Angeles puppetry was offered as a major course in the theatre-arts department. American industry has made extensive use of puppets for training its personnel, instructing the public, and creating markets. It is perhaps in this field that American puppetry comes closest to the puppetry of eastern Europe: in Poland and Russia, with hundreds on the staffs of the state theatres, the puppet stage concentrates on building attitudes favourable to the government which supports it. Increasing use of puppetry in education and television suggests

an ongoing strength. Like its parent art form, the theatre, puppetry often appears to be the eternal invalid which never dies.

ORGANIZATIONS

The Union Internationale des Marionnettes was organized in Prague in 1928 with Jan Malík (later of the National Czechoslovakian Puppet Theatre) as its first secretary. Since World War II it has regularly held international meetings attended mainly by persons from European and Asiatic countries. In North America the Puppeteers of America, organized in 1937, publishes *The Puppetry Journal* and holds an annual festival. Many cities, states, and provinces have their own organizations. The British Puppet and Model Theatre Guild, founded in London in 1926, serves as headquarters for puppetry in England and Wales along with the Educational Puppetry Association. Most of the major countries of Europe have comparable organizations.

PUPPIS, one of the three southern constellations into which the large Ptolemaic constellation Argo was subdivided. The bright new star Nova Puppis was visible during the winter of 1942.

PURĀNAS, ancient Indian compilations in Sanskrit verse on religious and legendary themes, the origin of which is traceable to Vedic times. They share much material with the two great epics, the *Mahābhārata* and *Rāmāyaṇa* (q.v.), and with the law books (*dharma-sāstra*). "Purāṇa" means "ancient," and, traditionally, a *purāṇa* treats of the creation of the world, its destruction and renewal, the genealogy of gods and seers, the great ages of mankind, and the history of dynasties. However, of the 18 principal surviving *purāṇas*, the majority are of sectarian character, concerned with devotion to Śiva or Viṣṇu (Vishnu; see **HINDUISM**). They contain much devotional material (*bhakti*), eulogies on shrines, the duties of the castes, and descriptions of Vedic-brahmanical customs and ceremonies. Recitation and exposition of *purāṇa* in temples and annually in Brahman households form an important aspect of Hindu devotion. See also the article **SANSKRIT LITERATURE** and its bibliography. (J. E. B. G.)

PURCELL, EDWARD MILLS (1912–), U.S. physicist, Nobel Prize winner for research on magnetic resonance, was born in Taylorville, Ill., Aug. 30, 1912. He received his B.S. from Purdue in 1933, and his Ph.D. from Harvard in 1938. During the war he was head of the Advanced Development group on radar problems at the radiation laboratory of the Massachusetts Institute of Technology. He became professor of physics at Harvard in 1949. He was awarded the Nobel Prize in 1952 jointly with Felix Bloch (q.v.) for the discovery of nuclear magnetic resonance in solids, a phenomenon observed independently for the first time at Harvard and Stanford. These investigators showed that by the absorption of radio-frequency waves in solids it is possible to detect nuclear magnetic moments. This research opened up a whole new field of physics: magnetic resonance spectroscopy. It yielded information not only on nuclear moments, but also on chemical bonds and atomic binding in liquids and solids, even supplying data on the structure of hydrocarbons useful for the oil industry. Another notable achievement of Purcell was the detection jointly with Harold I. Ewen in 1952 of the 21 cm. line of neutral atomic hydrogen in extraterrestrial radiation. This discovery added a new dimension to radio astronomy by revealing the distribution of hydrogen in galaxies. Purcell was appointed to his second term on the President's Science Advisory Committee in 1962.

See V. Torrey, "Changing Partners in the Atom Dance," *Saturday Review*, 44:68–69 (May 6, 1961). (J. H. V. V.)

PURCELL, HENRY (1659–1695), the most important English composer of his time, was born in the summer or autumn of

1659. His father was a gentleman of the Chapel Royal, where he himself received his earliest education as a chorister, first under Henry Cooke and then under Cooke's son-in-law Pelham Humfrey. When his voice broke in 1673 he was appointed assistant to John Hingston, keeper of the king's instruments, whom he succeeded in 1683. From 1674 to 1678 he tuned the organ at Westminster Abbey and was employed there in 1675-76 to copy organ parts of anthems. In 1677 he succeeded Matthew Locke as composer for Charles II's string orchestra (the "24 violins") and in 1679 was appointed organist of Westminster Abbey in succession to John Blow. A further appointment as one of the three organists of the Chapel Royal followed in 1682. He retained all his official posts through the reigns of James II and of William III and Mary. He married in 1680 or 1681 and had at least six children, three of whom died in infancy. His son Edward (1689-1740) was also a musician, as was Edward's son Edward Henry (b. 1716). Purcell seems to have spent all his life in Westminster; he died there on Nov. 21, 1695, possibly of the aftereffects of malnutrition in his early years. His fatal illness prevented him from finishing the music for *The Indian Queen*, which was completed by his brother Daniel (d. 1717). Daniel Purcell was also brought up as a chorister in the Chapel Royal and was organist of Magdalen College, Oxford, from 1688 to 1695. Before his brother's death he was little known as a composer, but from 1695 to 1707 he was in considerable demand for music for stage productions in London, until the advent of Italian opera brought his activities to an end.

BY COURTESY OF THE NATIONAL PORTRAIT GALLERY
HENRY PURCELL, PORTRAIT BY J. CLOSTERMAN

Purcell's music covers a wide field: the church, the stage, the court, and private entertainment. In all these branches of composition he showed an obvious admiration for the past combined with a willingness to learn from the present, particularly from his contemporaries in Italy. With alertness of mind went an individual invention which marked him as the most original English composer of his time, and one of the most original in Europe. This originality is found not only in his outstanding gifts as a melodist but also in his capacity for producing unexpected harmonic progressions by means of contrapuntal ingenuity.

To later ages Purcell was best known as a songwriter, because so many of his songs were printed in his lifetime and were reprinted again and again after his death. But the first evidence we have of his mastery is an instrumental work—a series of fantasias (or "fancies") for viols in three, four, five, six, and seven parts. The nine four-part fantasias all bear dates in the summer of 1680, and the others can hardly be later. Purcell was here reviving a form of music which was already out of date, and doing it with the skill of a veteran. It was probably about the same time that he started to work on a more fashionable type of instrumental music—a series of sonatas for two violins, bass viol, and organ (or harpsichord). Twelve of these were published in 1683, with a dedication to Charles II, and a further nine (together with a chaconne for the same combination) were issued by his widow in 1697. The foreword to the 1683 set claimed that the composer had "faithfully endeavour'd a just imitation of the most fam'd Italian Masters"; but side by side with the adoption of an Italianate manner there was a good deal that derived from the English tradition of chamber music.

It is the instrumental movements that are the most striking part of the earliest of Purcell's "Welcome Songs" for Charles II—a series of ceremonial odes which began in 1680. Possibly he lacked experience in writing for voices, at any rate on the scale required for works of this kind; or else he had not yet achieved the art of cloaking insipid words in significant music. By 1683 he had acquired a surer touch, and from that time until 1694, when he

wrote the last of the birthday odes for Queen Mary, he produced a series of compositions for the court in which the vitality of the music makes it easy to ignore the poverty of the words. The same qualities are apparent in the last of his odes for St. Cecilia's Day, written in 1692.

Purcell's genius as a composer for the stage was hampered by the fact that there was no public opera in London during his lifetime. Most of his theatre music consists simply of instrumental music and songs interpolated into spoken drama, though occasionally there were opportunities for more extended musical scenes. His contribution to the stage was in fact very modest until 1689, when he wrote *Dido and Aeneas* for performance at a girls' school in Chelsea; this miniature opera achieves a high degree of dramatic intensity within a narrow framework. From that time until his death he was constantly employed in writing music for the public theatres. These productions included some which gave scope for more than merely incidental music—notably *Dioclesian* (1690), adapted by Thomas Betterton from the tragedy *The Prophetess* by John Fletcher and Philip Massinger; *King Arthur* (1691) by Dryden, designed from the first as an entertainment with music; and *The Fairy Queen* (1692), an anonymous adaptation of Shakespeare's *A Midsummer Night's Dream*, in which the texts set to music are all interpolations. In these works Purcell showed not only a lively sense of comedy but also a gift of passionate expression which is often more exalted than the words. The tendency to identify himself still more closely with the Italian style is very noticeable in the later dramatic works, which often demand considerable agility from the soloists.

Purcell's four-part fantasias, his first court ode, and his first music for the theatre, *Theodosius*, all date from 1680. Some of his church music may be earlier than that, but it is not possible to assign definite dates. So far as is known, most of his anthems, whether for the full choir ("full anthems") or with sections for soloists ("verse anthems"), were written between 1680 and 1685, the year of Charles II's death. The decline of the Chapel Royal during the reigns of James II and of William and Mary may have been responsible for the comparatively few works he produced during that period; or, alternatively, he was so busy with stage music and odes that he had little time or inclination for church music. The style of his full anthems, like that of the fantasias, shows a great respect for older traditions. His verse anthems, on the other hand, were obviously influenced, in the first instance, by Humfrey, who had acquired a knowledge of Continental styles during his travels abroad. The most notable feature of these latter works is the use of expressive vocal declamation which is pathetic without being mawkish. The same characteristics appear in the sacred songs he wrote for private performance. Since composers for the Chapel Royal in Charles II's reign had the string orchestra at their disposal, Purcell took the opportunity to include overtures and ritornellos which are both dignified and lively. The most elaborate of all his compositions for the church are the anthem *My heart is inditing*, performed in Westminster Abbey at the coronation of James II, and the festival *Te Deum and Jubilate*, written for St. Cecilia's Day in 1694. Of these the anthem is the more impressive; the *Te Deum and Jubilate*, though they include sections of a more intimate character, suffer on the whole from a forced brilliance which seems to have faded with the passage of time.

Though the main period of Purcell's creative activity lasted for little more than 15 years, he managed to crowd into it a very large number of compositions, including more than 100 secular songs and about 40 duets, apart from those which he contributed to plays. Many of the songs are quite substantial pieces, incorporating recitative and arias on the lines of the Italian solo cantata. A favourite device which Purcell used widely in his secular music, though rarely in his anthems, was the ground bass (*q.v.*). This can have an invigorating effect in lively pieces, while in laments, such as Dido's farewell, it can intensify the expression of grief. The chaconne in the second set of sonatas uses the same technique with impressive results. Works of this kind represent the composer at the height of his capacity. The numerous catches, on the other hand, though accomplished enough, are

little more than an experienced musician's contribution to social merrymaking. Purcell seems to have abandoned instrumental chamber music after his early years. His keyboard music forms an even smaller part of his output: it consists of suites and shorter pieces (many adapted from other works) for harpsichord, and a handful of pieces for organ solo.

Apart from a large number of songs which appeared in vocal collections very little of Purcell's music was published in his lifetime. The principal works were the *Sonnatas of III parts* (1683); *Welcome to all the pleasures*, an ode for St. Cecilia's Day, written in 1683 (published in 1684); and *Dioclesian*, composed in 1690 (1691). After his death his widow published a collection of his harpsichord pieces (1696), instrumental music for the theatre (1697), and the *Te Deum and Jubilate* (1697), and the publisher Henry Playford issued a two-volume collection of songs entitled *Orpheus Britannicus* (1698 and 1702) which went through three editions. A few dramatic works, odes, and anthems were printed in the late 18th and early 19th centuries; but it was not until 1876, when the Purcell Society was founded, that a serious attempt was made to issue all of Purcell's works. The first volume was published in 1878, the second in 1882. From 1889 to 1928 volumes appeared at fairly frequent intervals. After that the scheme was in abeyance until it was revived in 1957 with the publication of a volume of miscellaneous odes and cantatas. It was finally completed in 32 volumes in 1965. Revision of earlier volumes proceeded simultaneously with the issue of later ones, beginning with a revised edition of *Dioclesian* in 1961.

PURCHAS, SAMUEL (c. 1577–1626), English compiler of works on travel and discovery, was born at Thaxted, Essex, and studied at St. John's College, Cambridge, and at Oxford. He was vicar first of a Thames-side parish in Essex and later in London where he was also chaplain to Archbishop G. Abbot) and met many seafarers. As an editor and compiler he sought to interest the general public of his day. In this he was very successful though his works have been severely criticized by scholars. They are however an indispensable source of information and contain many references to original accounts of voyages. His writings include: *Purchas, His Pilgrimage; or, Relations of the World and the Religions Observed in all Ages* (1613; other editions 1614, 1617, 1626); *Purchas, His Pilgrim. Microcosmus, or the Historie of Man* (1619); and *Hakluytus Posthumus or Purchas His Pilgrimes*, 4 vol. (1625; 20 vol., 1905–07).

See E. G. R. Taylor, "Samuel Purchas," *Geogr. J.*, vol. lxxv, pp. 536–55 (1930). (A. M. F.)

PURDAH: see HAREM.

PURGATORY, according to Roman Catholic faith, is a condition or state of suffering in which the souls of those who have died as friends of God pay the debt of temporal punishment and are purified from all possible stain of venial sin and evil habits. This teaching supposes that before death the sinner has been justified through the all-sufficient merits of Jesus Christ, internally renovated, made an adopted son of God, and freed from the debt of eternal punishment. In baptism the purification of the sinner is complete, every debt of justice satisfied. But if the friend and son of God sins grievously after baptism and is made righteous again in the sacrament of penance, though the eternal punishment is remitted through Christ's infinite merits, there remains as a debt some temporal punishment, a debt of expiation to be paid to God's justice in this life or the next. If the latter, the state of soul ensuing is precisely what the Catholic Church means by purgatory. The suffering of the soul detained therein derives all

its expiatory value from the merits of Christ. It may be helped to pay its debt by the suffrages of the living members of Christ's Body, that is, by their good works offered to God's mercy in Christ's name.

Protestants generally have denied the existence of purgatory consistently with their conception of imputed righteousness through faith in the merits of Jesus Christ. They leave no room or need for any further reparation by the justified sinner. Most Eastern Christians not united with Rome (Armenians, Jacobites, Nestorians, Greeks, Slavs, and others) also reject the doctrine of purgatory. Many Greco-Slav theologians have admitted the existence of a middle state between heaven and hell, but very few have conceded a state of expiatory suffering. Almost universally, however, these Eastern Christians believe that the dead can be helped by the prayers and good works of the living members of the church.

The doctrine is implied in the approval given to the belief and practice of the Jews in II Macc. 12:43–45. Some theologians appeal also to Paul's warning about the purification of apostolic workers after the revelation of their defects by God's judgment (I Cor. 3:10–15). Many places of the Old Testament are cited to justify a belief in temporal punishment to be endured after sin has been forgiven; e.g., God's pardon of the rebellious Israelites and the penalty imposed on them (Num. 14). Paul also seems to imply this truth in the afflictions, at least the untimely death, which he attributes to the unworthy reception of the Eucharist (I Cor. 11:27–32).

The principal argument for temporal punishment and purgatory is the practice of Christians from the early centuries and the teaching of the Fathers of the church concerning the value of penitential works, almsgiving, prayer, and the eucharistic sacrifice, through the merits of Christ, for the expiation of one's own sins, even pardoned sins, and the succoring of the souls of the dead.

Concerning the questions of place, duration, and nature of the pains of purgatory, there is no certain and definitive teaching. The fire of purgatory may possibly be metaphorical, symbolizing the suffering of the soul in its ardent though patient longing for complete purification and admission to the vision of God. With the Last Judgment purgatory will cease to exist.

PURI, a town and administrative centre of a district of Orissa state, India, is situated on the shore of the Bay of Bengal, 311 mi. (500 km.) SW of Calcutta and 776 mi. (1,249 km.) NE of Madras. Pop. (1961) 60,815. The old name of the town was Purushottam Puri (the city of the Greatest Being), abbreviated to Puri in common usage. William Bruton, the first European to visit the town (1633), called it "the great city of Jaggarnat." As the seat of the well-known shrine of Jagannath (see JUGGERNAUT), Puri is one of the most sacred places of pilgrimage for Hindus. The temple of Jagannath was built in the 12th century by Choda Ganga (the greatest of the eastern Ganga kings) and consists of a suite of three chambers, the dancing hall, the audience hall and the sanctuary with its images. About two miles from the temple is the Garden house (Gundicha ghara), the retreat of Jagannath to which his image, mounted on a huge car or *rath* (followed by smaller cars of his brother and sister), is pulled by enthusiastic pilgrims during the car festival each summer. The rajas of Khurda, titular descendants of the ancient Hindu monarchs of Orissa, have been in charge of the temple since 1590. The town contains the summer castle of the state governor, the palace of the raja of Khurda, a college, an observatory, and many hotels and hospices (*dharamsalas*). The beach of Puri attracts many tourists.

PURI DISTRICT is a country of alluvial plains with hills and woods in the north and northeast. Pop. (1961) 1,865,439. Area 3,999 sq.mi. (10,357 sq.km.). The main river is the Kuakhai (a branch of the Katjori) which itself divides into two branches, the Daya and the Bhargavi, both flowing into Chilka lake. Chilka is one of the largest lakes in India (length 41 mi. [65 km.]; breadth

13 mi. [20 km.] in the north and 5 mi. [8 km.] in the south). Dotted with islands, it is saline and shallow and most suitable for fish breeding. A large quantity of fish is exported. The district is rich in antiquities. At Dhauli Hill are the rock edicts of Asoka (3rd century B.C.). Sisupalgarh is a fort of 2nd-1st century B.C. and Khandagiri contains the caves and inscriptions of Kharavela (1st century B.C.). Bhubaneswar (*q.v.*) is a city of temples and at Chandrabhaga is the Konarak (*q.v.*).

Khurda is the divisional headquarters of Eastern Railway, and has an arts college. There is a science college at Nirakarpur, and Satyabadi (a Brahmin village) is famous for Krishna worship (*sakhigopal*). This village in modern times was associated with the experiment of an open-air school initiated by Gopabandhu Das. At Atri is a hot sulfur spring around which a big annual fair takes place.

Puri first came under the British in 1803. Later events were the rebellion of the raja of Khurda (1804) and the rising of the *paiks* (peasant militia) in 1817-18. More than one-third of the population is said to have perished in the Orissa famine of 1866. (MA. M.; N. K. S.)

PURIFICATION denotes the ritual techniques used in many cultures to protect against what are held to be unclean, sinful, or otherwise undesirable situations. In a society with a strong sense of solidarity, if one man violates a tabu the whole community may feel itself menaced until he is purified.

Childbirth, puberty, marriage, warfare or bloodshed, and death are commonly marked by purifying rites. Contaminating factors may include foods (as the flesh of totem animals), persons (as menstruating women or persons of inferior caste), places, and so on. Rituals of purification may entail the use of water (as in baptism), mutilation (as in circumcision), fasting, prayer, and confession. See also ABLUTION; LUSTRATION; RITES AND CEREMONIES.

PURIM (FEAST OF LOTS): see JEWISH HOLIDAYS.

PURINES. The purines comprise a group of nitrogenous compounds, a few of which are of great importance in living cells. The first purine known was uric acid, which was discovered in human urinary calculi by the Swedish chemist C. Scheele in 1776. The naturally occurring purines include adenine and guanine, two essential building blocks of nucleic acids (*q.v.*), a group of compounds regarded as carriers of hereditary characteristics. Another well-known purine is caffeine which, along with theobromine and theophylline, gives the stimulating effect to drinks made from coffee beans, tea leaves and cocoa beans.

Chemically, purines are structurally related to the pyrimidines. They are bases because of their nitrogen content. All purines are derived from purine itself, a substance with the empirical formula $C_5H_4N_4$. The structural formula of purine is shown in the accompanying diagram in which each atom is numbered as indicated. The molecule can exist in two forms which are very readily interconvertible, a phenomenon known as tautomerization (see TAUTOMERISM). The change of structure in the tautomerization of purine consists of the migration of a labile hydrogen atom between the nitrogen atoms at position 7 and position 9.

The four hydrogen atoms in

purine (at positions 2, 6, 8 and either 7 or 9) may be substituted by other groups, such as hydroxyl (OH), amino (NH_2) or methyl (CH_3) groups. When a hydroxyl group is introduced at position 2, 6 or 8, another type of tautomerization is possible, since the H of the OH group may migrate to a neighbouring nitrogen atom. For instance, uric acid, which is 2:6:8-trihydroxypurine, exists in two tautomeric forms, A and B as shown below.

In form A, uric acid yields salts with metal ions, the hydrogen on oxygen being replaceable and thus making the substance an acid. Form B shows that substitution may occur on the 1 and 3 nitrogen atoms as in the methylated purines such as caffeine.

The following diagram outlines the relationships between the various naturally occurring purines. Starting with purine, and successively substituting hydroxyl groups for the hydrogen atoms attached to carbon, hypoxanthine, xanthine and uric acid are obtained. Most living cells can synthesize the important purines adenine and guanine from simpler precursors. Ingested purines, as well as those formed within the cell, are eventually oxidized to uric acid.

In man, this substance is excreted in the urine as the main end product of purine metabolism. Other mammals excrete allantoin, a degradation product of uric acid. In reptiles and birds, however, uric acid is the main nitrogenous end product of protein as well as of purine metabolism. The excrement of birds and snakes,

therefore, consists mainly of uric acid. A rich source of uric acid, guano, the excrement of certain South American sea birds, has been accumulating, with the help of a dry climate, for untold years.

Because uric acid and its monosodium salt are relatively insoluble, they are readily precipitated. Such precipitates constitute the painful nodules characteristic of the disease gout in human beings. The pig is deficient in enzymes which convert guanine to allantoin, and consequently the pig frequently suffers from a form of gout similar in all respects to that in humans, except that the deposit in the joints consists of crystalline guanine instead of acid sodium urate.

Much of the fundamental work on purine chemistry was done by the German chemist Emil Fischer, who coined the name purine from the Latin words *purum* and *uricum*, the latter being chosen because the best-known purine at that time, uric acid, occurs in the urine.

Any modern text book of biochemistry will give further information on this subject. (B. V.)

PURITANISM, the most dynamic form of Protestantism among English-speaking peoples during the 16th and 17th centuries. The age of Puritanism in England may be roughly defined as the century following the Reformation (*q.v.*). It extended from the first years of the reign of Elizabeth I to 1660, when the restoration of the Stuarts brought to an end the attempt to fashion a Puritan state. The Puritan age in New England dated from the first settlement in 1620 to Massachusetts' loss of the old charter and the issuance of a new one in 1691, although there was to be a brief attempt to reconstitute the old order upon a new basis during the 1730s under the leadership of Jonathan Edwards.

The term Puritan was coined as an epithet of contempt during the 1560s, and it was applied to all those persons within the Church of England who sought a more thoroughgoing reformation of the church than had been provided by the Elizabethan religious settlement. It also came to be applied to those who broke away from the Church of England in order to carry out the desired reforms without further delay. The major body of Puritans were Anglicans and remained so until the outbreak of the English Civil War in 1642 (*see CIVIL WAR, ENGLISH*). Most of them were moderate episcopalians in sympathy, although Presbyterian and congregationalist sentiment was to be found among them. Even the early Congregationalists of the Massachusetts Bay colony in North America professed themselves to be loyal members of the Church of England. The small non-Anglican wing of Puritanism was composed initially of "separatist" Congregationalists and Baptists, but during the regime of Oliver Cromwell, when religious groups multiplied in a vast profusion, the Society of Friends (Quakers), constituted the extreme left of the Puritan movement.

In North America there was a varying degree of Puritan influence in all the English colonies, but the term tended to be reserved to designate the "separatist" and "nonseparatist" Congregationalists who established the Plymouth and Massachusetts Bay colonies and spread out into the rest of what was to become known as New England.

Nature of Puritanism.—Puritanism arose out of a desire for liturgical reform, being given classic definition at its earliest stage by G. M. Trevelyan: "the religion of all those who wished either to 'purify' the usage of the established church from taint of popery or to worship separately by forms so 'purified'" (*England under the Stuarts*, 16th ed., London, 1933). Questions of polity and theology later were brought into the area of controversy, but the underlying spirit of religious and moral earnestness that had given rise to the initial demand for reform remained the most constant feature of Puritanism. As a consequence, a Puritan became identified quite correctly in the popular mind as one who followed a strict and closely regulated habit of life. Edwards gave expression to this aspect of Puritanism when he described the Christian's "practice of religion" in these words: "It may be said, not only to be his business at certain seasons, the business of Sabbath-days, or certain extraordinary times, or the business of a month, or a

year, or of seven years, or his business under certain circumstances; but *the business of his life*" (*The Works of Jonathan Edwards*, vol. i, p. 314, 10th ed., London, 1865). The Puritan was a spiritual athlete, characterized by an intense zeal for reform, a zeal to order everything—personal life, family life, worship, church, business affairs, political views, even recreation—in the light of God's demand upon him.

The daily routine of the Puritan usually involved private devotions at the hour of rising; family prayers with the reading of Scripture and the catechizing of children and servants; and the keeping of a spiritual diary in which the events of the day were closely scrutinized and an accounting made of moral successes and failures as well as note being taken of the signal evidences of divine grace or displeasure that had been disclosed during the course of the day. The whole thrust of Puritan preaching was designed to reinforce this systematic and carefully controlled pattern of life by sensitizing the conscience to the issues that must be faced from day to day by earnest Christians. A non-Puritan clergyman, Anthony Gilbert, in 1566 put this aspect of Puritanism vividly when he reported that his patron had said that "he could never go to any of these Genevan sermons that he came quiet home, . . . there was ever something that pricked his conscience; he always thought that they made their whole sermon against him. But in the reading of Mattins and Evensong at [St.] Paul's, or in my reading of my service in his chapel, he sayeth, he feelth no such thing, for he is never touched, but goeth merrily to his dinner."

These differing facets of the Puritan's concern make it evident that Puritanism was rooted in a vast sense of dissatisfaction with mediocre and halfhearted endeavour. This dissatisfaction, in turn, was rooted in a deep religious experience of dramatic intensity. The whole object of the Puritan was to experience the miracle of grace himself and to produce it in others. Thus Puritanism falls within the category of a religious revival, and it is analogous in many ways to earlier revivals that sprang from the preaching of the friars and to the later revivals associated with the names of John Wesley, George Whitefield and Gilbert Tennent.

Tudor Puritanism.—Under Henry VIII the authority of the Roman papacy had been formally abolished by a series of parliamentary acts, culminating in the Act of Supremacy of 1534, which declared the king to be "the only supreme head in earth of the Church of England." The few limited reforms of the Henrician period were followed by a rapid Protestant advance under the boy king Edward VI (1547–53). This was followed, in turn, by a restoration of Roman Catholicism under Queen Mary (1553–58). Many of the more prominent Protestant leaders, including the archbishop of Canterbury, were burned at the stake during the Marian regime; the revulsion occasioned by these executions, it has been said, guaranteed that England was to be a Protestant nation in the future. Of greater importance was the fact that the exile on the continent, into which many younger men were forced, proved to be a school for training of men upon whom Elizabeth of necessity was to depend for leadership in the English Church. When Elizabeth I came to the throne late in 1558, she was hailed by the returning exiles as the English Deborah who would restore the Church of England to what they regarded as its pristine purity. She was to frustrate rather than fulfill their hopes.

Elizabeth was committed to the Protestant cause for a variety of reasons, but she detested anything that smacked of Geneva, having been alienated by John Knox's attack upon the right of women to rule and being convinced that the Genevans were "overbold with God Almighty, making too many subtle scannings of his blessed will, as lawyers do with human testaments." It was, she believed, dangerous to royal power to have private men citing Scripture against the government. Elizabeth was determined to exercise power in both state and church as her royal prerogative, and she was especially determined that the religious settlement should follow a middle course. Under pressure from the crown parliament passed an Act of Uniformity which required several observances that most Protestants regarded as popish superstitions. It was at this point, however, that a division occurred.

Some remembered Peter's word that one must obey God rather than men; these were to be the Puritans. Others remembered Paul's counsel that due regard must be given to constituted authority; these were to be the apologists for the Elizabethan settlement who insisted that a godly prince, after the pattern of Israel, must be obeyed in all matters not clearly proscribed in Scripture.

The initial controversy had been foreshadowed in the reign of Edward VI when Knox objected to kneeling as a practice associated with the adoration of the host and indicating a belief in transubstantiation, and when John Hooper objected to a distinctive clerical garb as representing in symbolic form a denial of the priesthood of believers. It was this latter issue that came to the front with the publication of Matthew Parker's *Advertisements* in 1566 as part of the effort to secure uniformity of clerical dress, and resulted in the label of "Puritan" being attached to the dissident party. The Puritans, of course, were seeking to reform the whole liturgy of the church that it might have greater theological integrity; and a rightly ordered worship, they believed, also involved the recovery of gospel discipline within the church. Their program was made explicit in 1572 in *An Admonition to Parliament*, which declared that "we in England are so far off from having a church rightly reformed according to the prescript of God's Word, that as yet we are not come to the outward face of the same." The "outward marks whereby a true Christian church is known," it continued, "are preaching of the Word purely, ministering of the sacraments sincerely, and ecclesiastical discipline which consisteth in admonition and correction of faults severely"; on all three counts the provisions of the Elizabethan settlement were deemed defective.

Puritan sentiment was strong enough in 1563 to come within one vote of adopting a sweeping program of reform in the Convocation of Canterbury, the legislative body for most of the Church of England. Defeated there, the Puritans turned to parliament where they were able to command majority support throughout Elizabeth's reign, but Elizabeth always claimed her prerogative and prevented parliament from dealing with the religious question. Edmund Grindal, archbishop of Canterbury, encouraged the voluntary implementation of a portion of the Puritan program, and this led to his being sequestered from office. While official efforts at reform were rebuffed by the queen, and while she was careful to prevent any widespread organization from being developed, a great deal of latitude and freedom was permitted within the parishes; and it was within the parishes, by virtue of effective preaching and pastoral example, that Puritanism continued to gain strength throughout the Elizabethan period. During this period also there were a few ardent and impetuous spirits who had become impatient with delay and who, adopting as their slogan "reformation without tarrying for any," proceeded to organize "separate" congregations. Ultimately most of these separatists were forced to take refuge in the Netherlands.

Stuart Puritanism.—Puritan confidence in the rightness of their cause may well have been the source of the optimism with which they greeted each new monarch. They were especially hopeful when after Elizabeth's death James I came to the throne in 1603. A dozen years earlier, as James VI of Scotland, he had consented to the establishment of Presbyterianism in his native land. The Puritans believed, therefore, that he might be expected to show some favour to Puritanism in England. With high expectations the Puritans presented the new king with a moderate plea for church reform known as the Millenary petition because it purported to represent the desires of more than 1,000 clergymen. The king promised a conference at Hampton court on the matter. When he met with them in Jan. 1604, he rejected the Puritan plea with scorn. James was an ardent Calvinist, but he was no presbyterian; far from restricting the power of the bishops, his dictum was "No bishop, no king."

One consequence of James's attempted repression of Puritanism was to drive additional Puritans into separatism and exile. Among these groups of exiles was the Gainsborough-Scrooby congregation, one portion of which went to Amsterdam under the leadership of John Smyth, where they became the earliest group of English Baptists. The Scrooby portion under the leadership of John

Robinson went to Leiden, from which in 1620 some of their number departed to establish the colony of Plymouth in the new world. Other Puritans, unwilling to renounce all bonds of fellowship with the Church of England, adopted a middle position which has been called nonseparatist congregationalism. Chiefly under the guidance of Henry Jacob and William Ames, they developed the theory that the Church of England was in essence composed of congregational churches; this fact had been obscured but it had not been obliterated. Thus they were justified in forming independent congregations when necessary and at the same time professing themselves to be loyal members of the Church of England. Nonseparatists of this type established the Massachusetts Bay colony in 1629.

James I, however, was not an effective persecutor, and his policy was moderated by the influence of Archbishop George Abbot, who was sympathetic to the Puritan cause. By virtue of various expedients, many of the clergy were able to retain a measure of freedom in their parishes, and a system of lectureships was developed to provide for those who could not. The lectureships were preaching stations set up voluntarily, and they permitted the occupants to escape from the necessity of reading the required service. Serious trouble developed only after the accession of Charles I in 1625. Under the aegis of William Laud (q.v.), archbishop of Canterbury, rigorous measures were adopted to enforce conformity, lectureships were suppressed and when parliament proved to be refractory Charles embarked upon a period of personal rule that lasted through the 1630s.

Puritan Revolution.—As the result of an attempt to impose "Laud's liturgy" on the Scottish Church, Scotland rose in revolt and in 1639 invaded England. Charles was without adequate financial resources to carry on a war and was forced to summon parliament in 1640. Parliament immediately took command of the situation, refusing to grant necessary subsidies until the abuses of Charles's personal rule had been remedied. There was general agreement that the evils of prelacy should be eliminated, but when parliament abolished episcopacy the king was able to rally support; civil war broke out in 1642 (see CIVIL WAR, ENGLISH). The Westminster assembly of divines was summoned in 1643 to draft a new religious settlement for the nation, but its essentially presbyterian proposals were unsatisfactory for a variety of reasons to a majority of the people. The more erastian members of parliament did not look with favour upon the establishment of an independent ecclesiastical system. Large segments of the population remained strongly episcopalian in their sympathies. There had also been a vast proliferation of smaller religious groups since the lifting of the restraints of the Laudian regime. Furthermore, the Puritan preachers, who for three generations had been insisting upon the necessity for the Word of God to be freely preached, had cultivated a climate of opinion among many of their followers that was hostile to the placing of new restrictions upon the freedom to preach. Most important of all, widespread sentiment for religious toleration had developed in the parliamentary army. This was "the good old cause" that held the army together in its struggle with the king, and to the army the proposals of the assembly represented the substitution of one repressive ecclesiastical system for another. John Milton spoke for the army when he said: "New presbyter is but old priest writ large."

With parliament becoming increasingly divided and impotent, effective rule shifted to the army under the leadership of Cromwell. The royalists were brought under control in a series of battles, the king was executed and the religious problem was resolved in terms of a voluntary national establishment. Cromwell was less successful in his efforts to shift authority from the army to a stable parliamentary regime. The nation was too divided for any of the expedients he devised to succeed. After his death and the removal of his strong hand, the political situation rapidly deteriorated, and in 1660 the Puritan attempt to fashion a new commonwealth was brought to an end with the restoration of the monarchy. The religious issue remained troublesome, however, until the adoption of the Act of Toleration in 1689.

American Puritanism.—The term Puritan has been given a much narrower definition in the United States. There was a con-

spacious Puritan influence in early Virginia, and the blue laws of that colony have been said to have been even more repressive than those of New England. Moreover a Puritan influence was represented to varying degrees in all the English colonies by Baptists, Quakers and English Presbyterians. Puritanism in America, however, is generally understood to mean the early Congregationalism of New England.

Massachusetts Bay, the strongest of the New England colonies, was founded by a group of nonseparatist Congregationalists who had become convinced—as a result of the dissolution of parliament in 1629 by Charles I and the adoption of the rigorous repressive measures of Laud—that it was no longer possible to reform the Anglican Church in England. Through a defect in the charter they were able to transfer the government of the colony to the new world, and throughout the Laudian decade of the 1630s a large and well-organized migration into the new colony proceeded. No colony in the history of European colonization ranked above Massachusetts Bay in wealth, station, education or capacity. The colonists were a selected people ("sifted grain") with strong clerical leadership, and their purpose was to accomplish in the new world that which they had been prevented from accomplishing at home. Their intention was to create in the American wilderness a new Zion that would become "a city set on a hill" and force by the power of its example the desired reformation in England.

The Massachusetts Bay Puritans established what they believed to be a biblical church order and with it a community that was regulated throughout by divine and natural law. The whole program was outlined in the *Cambridge Platform* of 1648. Church membership was restricted to the regenerate and their children who should "own the covenant," and only church members enjoyed political rights. Religious uniformity was enforced, and dissenters were informed that they had the right to stay away or to cross the river and take up land of their own beyond the boundary of Massachusetts. The restrictions were difficult to maintain; there were demands that the franchise be broadened and religious dissent kept appearing. When Roger Williams was banished, the settlement he established at Providence became a new source of dissidence. The second generation saw a diminution of zeal. The clergy interpreted recurrent misfortunes as signs of God's wrath with the growing laxity, but the adoption of the "halfway covenant" was evidence of clerical inability to halt the trend. The replacement of the charter in 1691 put an end to any real hope they still entertained of maintaining their holy commonwealth in its purity. The story was much the same in the other Puritan colonies of New England. Edwards briefly rallied the waning forces of Puritan zeal, and attenuated Congregational establishments lingered on in Massachusetts, Connecticut and New Hampshire until the 19th century. The Puritan heritage, however, was stamped deep in the character of the New Englanders, and with the great migration westward it became a major factor in the shaping of the American spirit.

Puritan Contributions.—One of the most conspicuous contributions of Puritanism was the sturdiness of character it produced. "The Puritan mind was one of the toughest the world has ever had to deal with. It is inconceivable to conceive of a disillusioned Puritan; no matter what misfortune befell him, no matter how often or how tragically his fellowmen failed him, he would have been prepared for the worst, and would have expected no better" (Perry Miller and T. H. Johnson, *The Puritans*, pp. 59–60, New York, 1938). The Puritan knew that the life of faith is an arduous struggle, that sin is a stubborn fact of human existence and that affliction is frequently the lot of the saints; but he was nerve and strengthened by a great devotion to God and by a great confidence in God's overruling Providence. Later generations were fed again and again from the devotional works the Puritans produced.

Curiously, the Puritans, who began as firm believers in the necessity for religious uniformity, became the architects who fashioned the principles of religious freedom. This was partly the result of the fact that the religious diversity they generated bred of necessity a spirit of toleration, but the necessity was

supported by theological convictions whose implications only gradually became fully apparent. They had emphasized the necessity for the Word of God to be freely preached, and they recognized that even the best of men and churches were fallible. Who was to decide who might preach, when God might speak through the humblest of the brethren? Thus the New England Puritans could pursue measures of repression only with a lurking sense of guilt, elaborate apologetics and a tendency to make increasing concessions to dissent. More typical of the logic of Puritanism was Williams' *Bloudy Tenent of Persecution*, which became one of the great Puritan manifestoes in the English civil wars.

Many scholars have noted the contribution of Puritanism to the development of democracy. The army debates, the gathered churches, the demand for liberty and the denunciations of arbitrary power all helped create a climate of opinion favourable to the development of self-government. Even more important was the insistence upon the necessity for checks and balances if the abuse of power was to be prevented. Said John Cotton: "Let all the world learn to give mortal man no greater power than they are content they shall use, for use it they will . . . It is necessary that all power that is on earth be limited, church power or other. . . . It is counted a matter of danger to the state to limit prerogatives, but it is a further danger not to have them limited" (*An Exposition of the Thirteenth Chapter of Revelation*, p. 72). The relationship that has been suggested between Puritanism and the rise of modern capitalism is more debatable. See also references under "Puritanism" in the Index.

PURITY, BRETHREN OF, the usual English designation of the IKHWAN AS-SAFA' (i.e., "Sincere Brethren"), an Arabic secret confraternity who produced, probably in the second half of the 10th century A.D., a philosophical and religious encyclopaedia consisting of 52 "writings" (Arabic *rasa'il*; sing. *risala*) by different authors. The contents of this encyclopaedia appealed to the Ismailian movement, but its authors were not Ismaili themselves. Like all other Islamic philosophers, they attempted to naturalize Greek philosophy in a way of their own, but they differ from other Islamic philosophers in following a more orthodox Neoplatonic line and in admitting Hermetic, Gnostic, astrological and occult sciences on a large scale. According to them, the individual human souls emanate from the universal soul and rejoin it after death; and the universal soul in its turn will be united with God on the day of the Last Judgment.

Rasa'il 1–14 deal with the preparatory sciences such as mathematics, astronomy and astrology, music, geography and the different parts of Aristotelian logic (*risala* 13 was translated into Latin in the middle ages); *rasa'il* 15–31 with the natural sciences in the order established by the later Greek commentators of Aristotle and also with man as a microcosm, with the human soul, with the influence of the stars and with the difference of languages (see below for *risala* 22); *rasa'il* 32–41 with the spiritual world on Neoplatonic lines, with the final destruction of the world, with the longing of the soul for God and its spiritual resurrection, etc.; and *rasa'il* 42–52 with various aspects of the revealed divine law, with the mutual duties of the brethren, with prophetic revelation and with miracles, magic, etc. There is also an important summary of the whole encyclopaedia, *Ar-Risala al-Jami'a*. *Risala* 22 tells the story of a dispute between animals and men before the king of the genii (in which the animals eventually lose). This story was translated into Catalan by a Franciscan friar, Anselmo de Turmeda, in 1417 (he represented it as his own original work) and into English by way of a Hindustani version, by J. Wall (1863).

Apart from Arabic editions of the whole encyclopaedia, 4 vol. (1888–89), and of the summary, critical ed., 2 vol. (1949–51), there are German translations of several of the *rasa'il* by F. Dieterici (*Die Naturanschauung und Naturphilosophie der Araber*

..., 2 parts, 1876-79; and *Die Abhandlungen der Ichwan es-Safa im Auswahl*, 3 parts, 1883-86). Dieterici, however, was unaware of certain Islamic aspects of the work and overrated its philosophical importance.

PURKINJE, JOHANNES EVANGELISTA (JAN EVANGELISTA PURKYNE) (1787-1869), Czech physiologist, a pioneer in experimental physiology, histology, and embryology, was born in Libochovice, near Prague, Dec. 17, 1787. He graduated in medicine at Prague in 1819 and in 1823 became professor of physiology and pathology at Breslau University, where he began a course of experimental physiology, established a small laboratory, and created an independent department of physiology (1839), the first of its kind. He established another after becoming professor at Prague University (1850). He died in Prague, July 28, 1869.

Purkinje's scientific work was extremely varied, the most important concerning vision and microscopy. He noticed similar granular formations in different animal tissues and drew attention to the analogy of these animal granules (Ger. *Körnchen*) with plant cells (1837); and he introduced the term protoplasm. Some of his discoveries bear his name: Purkinje's cells in the cerebellar cortex; Purkinje's fibres; the large heart muscle cells beneath the endocardium, forming Purkinje's network; Purkinje's germinal vesicle, the nucleus of the ovum; Purkinje's figure, the shadows of the retinal vessels; Purkinje's images, the reflections on the surfaces of cornea and lens of the eye; Purkinje's phenomenon, the change in the brightness of blue and red in the dark.

Publication of Purkinje's *Omnia Opera* began in 1918.

PURNEA, a town and district in the Bhagalpur division of Bihar, India. The town, headquarters of the district, lies near the left bank of the Saura River, a tributary of the Ganges, and 50 mi. (80 km.) NE of Bhagalpur. Pop. (1961) 40,602. It is a nodal town with a brisk trade in rice and raw jute.

PURNEA DISTRICT (area 4,259 sq.mi. [10,372 sq.km.]; pop. [1961] 3,089,128) occupies the eastern part of the North Bihar Plains bordering West Bengal and is traversed by meandering streams and abandoned courses of the Kosi River. The Mahananda is the principal river of the district. Rice and jute are the chief crops; others include tobacco and mustard seeds. Katihar (pop. [1961] 46,837), to the south, is the largest town and an important railway junction and trade centre. Kishanganj, near the Mahananda River, and Forbesganj, near the Nepal frontier, are the other trade centres. The district is served by the North Eastern Railway. (S. P. C.)

PURPLE, a shade varying between crimson and violet. Formerly it was the deep crimson colour called in Latin *purpura*, from the name of the shellfish (*Purpura*) which yielded the famous Tyrian dye. Tyrian purple during many ages was the most celebrated of all dyed colours, and possibly the first to be permanently fixed on wool or linen. Being extremely costly, robes of this colour were worn as a mark of imperial or royal rank, whence the phrase "born in the purple." In the Roman Catholic Church "promotion to the purple" is promotion to the rank of cardinal.

The ancients derived their purple from the mollusks, *Purpura haemastoma*, and *Murex brandaris*, the shells of which have been found adjacent to ancient dyeworks at Athens and Pompeii. The colour-producing secretion is contained in a small cyst adjacent to the head of the animal, and this puslike matter when spread on textile material in presence of sunlight develops a purple-red colour. P. Friedländer showed that the dye developed from the mollusks is 6:6'-dibromindigotin. (A. G. P.; X.)

PURPURA is the presence of large (ecchymoses) and small (petechiae) hemorrhages in the skin, often associated with bleeding from natural cavities and in tissues. It occurs as a result of failure of hemostasis which, in turn, has five major causes:

1. Damage to the wall of small arterial vessels (vascular pur-

pura), due to vitamin deficiency (scurvy), bacteria, viruses, allergic reactions, etc. A hereditary disease in which the vessels appear normal but cannot contract after injury is known as pseudohemophilia.

2. Deficiency of platelets, small bodies that not only plug leakages in the vessel wall mechanically but also contain many chemicals active in the coagulation of blood. Bleeding occurs when platelets are insufficient in number (thrombocytopenia) either because they are not produced (as a result of destruction of the precursor megakaryocytes in the bone marrow, due to invasion by leukemia or to aplasia induced by drugs or by radiation injury) or because they are too quickly destroyed by an overactive spleen or by antibodies (immunothrombocytopenia). Platelet antibodies develop in the course of other diseases (such as lupus erythematosus) or may be evoked by allergy to viruses, bacteria, or certain drugs. Spleen and antibodies are usually associated in destroying platelets. In one variety of the disease (thrombocytopenic purpura) the platelets are normal in number but abnormal in function.

3. Deficiency of clotting factors, either congenital (as in hemophilia, Christmas disease, hypoprothrombinemia, afibrinogenemia, etc.) or acquired in the course of disease (especially of liver), administration of drugs (anticoagulants, etc.).

4. Development of circulating anticoagulants of various types (abnormal proteins, antibodies, etc.) that prevent normal interaction of the various clotting factors and are found in some blood disorders (multiple myeloma, leukemias, etc.), following reactions to drugs, in diseases of the connective tissue, and in radiation injury.

5. Fibrinolysis, due to the activation of a usually dormant system that is able to destroy the blood fibrin clot; this may occur during accidents of pregnancy, delivery, and surgery. A paradoxical type of bleeding is found when tissue materials (as in shock, trauma, burns, etc.) enter the bloodstream and cause clotting within the vessels. As the patient is depleted of clotting factors, he becomes a bleeder. This mechanism is often found behind severe hemorrhage at delivery.

Treatment of purpura depends on the causative mechanism. ACTH and steroid hormones are effective in controlling vascular purpura and the bleeding of thrombocytopenia. Transfusion of platelets may be a useful technique for bleeding emergency, and surgical removal of the spleen is resorted to in thrombocytopenic purpura when other therapy has failed. The administration of either blood or plasma or of the fractions specifically absent (fibrinogen, antihemophilic globulin, etc.) is the basis of the treatment of acute bleeding in disorders of blood coagulation. See also BLOOD; BLOOD, DISORDERS OF; *Purpura*; HEMORRHAGE.

See M. Stefanini and W. Dameshek, *Hemorrhagic Disorders* (1955). (M. Sr.)

PURSLANE, the common name for certain small fleshy annual plants of the genus *Portulaca*, with prostrate, reddish stems, egg-shaped leaves attached by the narrower end, and small yellow flowers that open in the sunlight. The common purslane (*P. oleracea*), or pusley, is a widespread weed, but is grown to some extent as a potherb, mostly in Europe. All plants of the genus are known for their ability to persist: they grow well even in dry, waste soil and can retain enough moisture to bloom and ripen seeds long after they have been uprooted. The capsules, which open by a lid, scatter many small seeds of great longevity. The purslane tree (*Portulacaria afra*), native of South Africa, is a fleshy leaved, soft-wooded tree up to 12 ft. high; it is grown in California as a specimen plant for its succulent habit and its tiny pink flowers in clusters.

PURULIA, a town and district in the Burdwan division of West Bengal, India. The town, headquarters of the district, is a straggling settlement, about 1 mi. N of the Kasai River and 135 mi. WNW of Calcutta. Pop. (1961) 48,134. It lies largely to the southwest of the junction of the Asansol-Chandil railway line with the Ranchi-Purulia branch and is a focus of good metalled roads. The town has a radial pattern; there are several tanks (artificial ponds), the largest one (1½ mi. in perimeter) being to the north.

PURULIA DISTRICT has an area of 2,415 sq.mi. (6,285 sq.km.) and a population (1961) of 1,360,016. The present district was formed at the reorganization of states in 1956 from the transferred area of the former Manbhum District of Bihar (with the exception of the thanas [police stations] of Chas, Chandil, Patamda, and Ichagarh, which were retained by Bihar).

Much of the district is an undulating peneplain, 500–1,000 ft. (160–330 m.) above sea level, forming the eastern fringe of the Chota Nagpur Uplands. Toward the west and south are forested scarps overlooking the Subarnarekha Valley. Forests occur in small isolated patches, and the district is dotted with tanks used for irrigation. The flood control and irrigation scheme on the Kasai River consists of a dam, 10 mi. (16 km.) W of the town of Purulia, and a reservoir. The principal crop is rice, which covers 72% of the sown area. Shellac is manufactured in the towns of Purulia, Jhalda, and Balrampur. (E. AH.)

PURVA MIMAMSA, one of the six schools of thought to which Indian philosophers adhered in the centuries following the Epic period. See **INDIAN PHILOSOPHY: Six Systems**.

PURVEYANCE, in England, the compulsory purchase of goods for the king and the compulsory hire of horses and carts to convey the goods, was a standing grievance through the Middle Ages and into the 17th century. Payment was made at "the king's price," a wholesale price less than that current in the local markets. The king's officers exercised this right at the great fairs and took a customary levy of wine coming into the ports. In this way the king's manors were restocked and his castles repaired and provisioned. The first limitation of this prerogative was won in Magna Carta (1215) when the king promised immediate payment for goods taken and that horses and carts should not be seized for carriage duty nor timber for the repair of castles, save with the owner's consent (cap. 28, 30, 31). Although the final version of Magna Carta allowed royal officers to delay payment where there was a royal castle, it exempted the demesne carts of parsons, knights, and ladies from being taken. It was often alleged that the king's officers took more than the king needed and sold the goods for their own profit, and, moreover, did not pay for what they seized. In 1258 the barons complained in their Petition (cap. 23) that because "almost no payment" was made for goods taken, English merchants were impoverished and foreign merchants would not import goods.

Edward I tried to regulate the behaviour of those taking prisages on his behalf in the first Statute of Westminster (1275); but general exactions were made necessary by his campaigns and a long clause dealing with abuses was included in the *Articuli super carias* (1300). The *Articuli*, however, never became substantive law. The king's obligation to provide hospitality meant that purveyance must be regulated rather than abandoned and it was regulation, not abolition, that was demanded in the 14th century. But the growing complexity of the royal household and the establishment of households for other members of the royal family increased the burden. In the Good Parliament (1376) the Commons petitioned that the justices of the peace should be commissioned to enforce recent statutes against dishonest purveyors, but this was not secured by statute until 1441. By 1600 it was the practice for the justices of the peace to fix with the officers of the Board of Green Cloth (the household accounting office) the price and amount of provisions required; the difference between the agreed and current market prices was raised by county assessments. There were still loopholes for abuse and Sir Francis Bacon spoke against purveyors in the first parliament of James I. Purveyance fell out of use under the Commonwealth and was abolished in 1660 at the Restoration. Even then, the royalist, Fabian Philipps, protested, arguing that purveyance kept taxes and prices down.

PURVITS, VILHELMS KARLIS (1872–1945), Latvian landscape painter who introduced Impressionism into northeastern Europe, was born in Zaube rural district on March 3, 1872, and

attended a secondary school in Latgale Province. He later abandoned his father's milling business for painting, graduating from St. Petersburg Academy in 1897; awarded a Rome prize, he traveled widely in western Europe. After teaching at Tallinn Cathedral School (1906–09) he directed the Riga State Art School until it was closed in 1916; from 1913, when he was elected academicien of St. Petersburg Academy, he was also director of the state museum and professor at Riga University.

Purvits organized the independent Latvian Academy of Arts in 1919 and was its rector and professor until 1934. In 1934–36 he edited a history of art. From Impressionism he developed the Baltic landscape style; later, his methodical compositions became more colourful and expressionistic.

Many of his pictures were destroyed by military action at Jelgava, Latvia, in July 1944; others, evacuated to Bavaria, disappeared. A refugee, Purvits died at Nauheim, Hesse, Ger., on Jan. 18, 1945.

PUSA, a village in Bihar, India, about 40 mi. (64 km.) NE of Patna. In 1796 the government acquired an estate there which was long used as a stud depot and afterward as a tobacco farm. The estate of 1,280 ac. (518 ha.) was made over in 1904 to the Imperial Agricultural Department of the government of India and became its headquarters. In 1905 a research institute was founded with an experimental farm and an agricultural college at which officers were trained for higher posts in the agricultural departments. The institute owed its inception to Lord Curzon, then viceroy, and rendered very useful service to Indian agriculture. A. and G. L. C. Howard produced strains of wheat which gave high yield and were of good milling quality; these strains were rust-resistant and gave good results under diverse conditions of soil and climate.

The Pusa varieties were in their day grown over large tracts of the United Provinces (now Uttar Pradesh), the Punjab, and the former North-West Frontier Province (West Pakistan). E. J. Butler carried out masterly researches there on fungus pests, as did H. M. Lefroy on insect pests troublesome in India. B. P. Pal and other Indian agricultural scientists also did good work. The advantages of selective breeding of cattle were demonstrated; the milk yield of a pure herd was doubled in ten years.

The institute always suffered from its isolated position, and when in 1934 an earthquake destroyed the main block of laboratories it was decided to transfer the work to New Delhi and to found a central research institute there. This plan was duly executed, and the new Indian Agricultural Research Institute was opened on Nov. 7, 1936, by the viceroy, Lord Linlithgow. In 1958 under the Universities Grants' Commission the institute was given the same standing as a university. The road on which the institute buildings stand is called Pusa Road. (E. J. R.)

PUSAN (Japanese **FUSAN**), a city located along a deep, well-sheltered bay at the southeast tip of Korea, facing the Korean strait. During Japanese control (1910–1945) Pusan became the major Korean port. Ferry services connected it to Shimonoseki, Japan. Rail lines through Korea to Manchuria and China terminated in Pusan. Industries, including shipbuilding, iron and steel, railroad shops and textile manufacturing were developed. Rice milling and salt refining were also carried on.

The beachhead area around Pusan was held by the United Nations forces in 1950, and the city became the temporary capital of the Republic of Korea and a port of supply and disembarkation during the first years of the Korean war. The city was swollen by refugees, whose many temporary shacks covered the hills. Disastrous fires occurred in these areas but the city was rebuilt and more permanent structures established. Industries were redeveloped and the population grew to 1,162,614 (1960 census).

(S. McC.)

PUSEY, EDWARD BOUVERIE (1800–1882), English leader of the Oxford movement, who, though remaining firm in his Anglican beliefs, headed the Catholic revival in the Church of England, was born at Pusey on Aug. 22, 1800. His father was Philip Bouverie, whose ancestor was a Protestant refugee from the Low Countries who reached England in the 16th century. Philip Bouverie took the name of Pusey upon succeeding to the estate

of that name in Berkshire. Edward was educated at Eton and Christ Church, Oxford. In 1823 he stood for a fellowship by examination at Oriel college and was elected, thus entering the brilliant common room of which John Keble and J. H. Newman (q.v.) were already members.

From 1825 to 1827 he studied oriental languages and theology in Germany, where the state of German Protestantism, driven to skepticism by the rationalism of the Enlightenment, made a permanent impression upon him by way of reaction.

In 1828 Pusey's reputation as an orientalist caused the duke of Wellington to nominate him to the regius chair of Hebrew in Oxford, which carried with it a canonry of Christ Church. From the year 1833 began his association with the Oxford movement, to which he brought a decisive reinforcement. "He," wrote Newman, "at once gave us a position and a name." He contributed a tract on fasting to the *Tracts for the Times* in 1834 and his most noteworthy work in that series was the extensive tract upon baptism of 1835.

In 1843 Pusey preached his university sermon on "The Holy Eucharist, a Comfort to the Penitent," which asserted the doctrine of the Real Presence. For this he was suspended by the vice-chancellor (without being allowed to speak publicly in his own defense) from preaching before the university for two years, an arbitrary act which, in H. P. Liddon's words, "sealed the doom of the old régime—the authority of the Heads and the old ecclesiastical polity of Oxford" and was a factor leading to university reform. Yet, after the ending of the sentence, Pusey preached in 1846 another sermon asserting another principle of the Oxford movement, the right of private confession and the existence of priestly absolution in the Church of England. Newman's secession to the Roman Catholic Church in 1845 was a crushing blow to Pusey.

Pusey's intense industry was devoted to the work of his professorial chair, to learned theological writing, to preaching and to individual spiritual direction. Nor were his activities confined to Oxford. In the cholera epidemic of 1866 he tended the sick in Bethnal Green; he preached in many parts of the country and contributed generously to church purposes, such as building St. Saviour's church, Leeds, at his own expense in 1842–45; and in addition, he was responsible for the revival of the monastic life in the Church of England, encouraging Marian Hughes to take religious vows (the first Anglican to do so since the Reformation) in 1841 and helping, in 1845, to found in London the first Anglican sisterhood.

In matters of biblical criticism Pusey was strictly conservative and to the end of his life combated the newer ideas which were becoming fashionable; his works on *The Minor Prophets*, with *Commentary* (1860) and *Daniel the Prophet* (1864) show a deep but old-fashioned Hebrew scholarship. Averse to the use of philosophy in theological construction, his doctrinal outlook was marked by a strong attachment to the principle of revelation interpreted by the historic authority of the church. He lacked Newman's speculative brilliance but had the intellectual strength of a well-stored and balanced mind and of a deep reverence for historic truth; he tested all current teaching by its consonance with the Bible and the mind of the early church.

Pusey's private life was marked by severe asceticism, intense personal religion, a capacity for lasting friendship and deep family affection. The death of his wife in 1839, of a daughter in 1844 and of his only son in 1880 were irreparable blows. He died on Sept. 16, 1882, at Ascot priory, the home of a sisterhood with which he was associated; he was buried in Christ Church cathedral.

Two years later his friends founded Pusey house, Oxford, as an institution for theological study and pastoral care in the university. There his library and many personal letters, papers and relics are preserved.

See H. P. Liddon, *Life of Edward Bouverie Pusey*, 4 vol. (1893–94), with a list of Pusey's works; and shorter biographies by G. W. E. Russell (1907) and G. L. Prestige (1933).

(T. M. P.)

PUSHKIN, ALEKSANDR SERGEEVICH (1799–1837), the greatest Russian poet, and the founder of modern Russian

literature, was born in Moscow on June 6 (new style; May 26, old style), 1799. His father came of an old boyar family; his mother was granddaughter of Abram Hannibal who, according to family tradition, was an Abyssinian princeling bought as a slave at Constantinople and adopted by Peter the Great, whose comrade in arms he became. Pushkin immortalized him in the unfinished historical novel *Arap Petra Velikogo* (1837; *The Negro of Peter the Great*).

Early Years.—Like many aristocratic families in early 19th-century Russia, Pushkin's parents adopted French culture, and he and his brother and sister learned to talk and to read in French. They were left much to the care of their maternal grandmother, who told Aleksandr, especially, stories of his ancestors in Russian; and from Arina Rodionovna, his old nurse, a freed serf (immortalized as Tatyana's nurse in *Eugeni Onegin*), he heard Russian folktales. During summers at his grandmother's estate near Moscow, he talked to the peasants, and spent hours alone, living in the dream-world of a precocious, imaginative child. He read widely in his father's library and gained stimulus from the literary guests who came to the house—Vasili Pushkin, his father's brother, a minor poet, I. I. Dmitriev, N. M. Karamzin, V. A. Zhukovski, and K. N. Batyushkov, young writers opposed to the prevailing French classicism.

In 1811 Pushkin entered the newly founded Imperial Lyceum at Tsarskoe Selo (later renamed Pushkin) and, while there, began his literary career with the publication (1814, in *Vestnik Evropy*, "The Messenger of Europe") of his verse-epistle "To My Friend, the Poet." In his early verse, he followed the style of his older contemporaries, the Romantic poets Batyushkov and Zhukovski, and of the French 17th- and 18th-century poets, especially the vicomte de Parny, and their tradition of light verse.

While at the Lyceum he also began his first completed major work, the romantic poem *Ruslan and Ludmila* (published 1820) written in the style of the narrative poems of Ariosto and Voltaire, but with an old Russian setting, and making use of Russian folklore. *Ruslan*, modeled on the ideal traditional Russian epic

hero, encounters various adventures before rescuing his bride, Ludmila, daughter of Vladimir, grand prince of Kiev, who, on her wedding night, has been kidnapped by the evil magician Chernomor. The poem flouted accepted rules and genres, and was violently attacked by both of the established literary schools of the day, classicism and sentimentalism. It brought Pushkin fame, however, and Zhukovski presented his portrait to the poet, with the inscription "To the victorious pupil from the defeated master."

St. Petersburg.—In 1817 Pushkin left the Lyceum, and, accepting a post in the foreign office at St. Petersburg, plunged into social life. He was elected

ALEKSANDR PUSHKIN, AN OIL PAINTING BY V. TROPININ, 1827. IN THE PUSHKIN MUSEUM, LENINGRAD

to the exclusive Arzamás, a literary society founded by his uncle's friends, and also became an active member of the "freedom" movement which had begun among the progressive aristocracy as a result of the upsurge of patriotism after the Napoleonic invasion of 1812.

Pushkin joined the "Green Lamp" association, which, though founded (in 1818) for discussion of literature and history, soon became a clandestine branch of a secret society, the "Union of Welfare." In his political verses and epigrams, widely circulated in manuscript, in the ode to liberty (*Volnost*, 1817); and in the *Derevnya* (1819; *The Village*), written under the influence of the 18th-century radical thinker and writer A. N. Radischev (q.v.) he made himself the mouthpiece of the ideas and aspirations of those who were to take part in the Decembrist rising of 1825.

Exile in the South.—For these political poems, in May 1820 Pushkin was banished from St. Petersburg to a remote southern province. Sent first to Yekaterinoslav (Dnepropetrovsk), he was there taken ill, and, while convalescing, traveled in the northern Caucasus, and later, to the Crimea, with Gen. Rayevski, a hero of 1812, and his family. The impressions he gained provided material for his "southern" cycle of romantic narrative poems.

The "Southern" Cycle.—Like many Western European writers, Pushkin had fallen under the spell of Byron's poetry, and, as he himself said, his southern poems "smack of Byron." They introduced Byronic Romanticism to Russia. But even in the first of them, *Kavkazski plemnik* (1822; *The Prisoner of the Caucasus*), realist tendencies are discernible. Pushkin here creates, from his own experience, a psychologically exact portrait of a typical representative of the rising generation in Russia, who, disappointed in love and friendship, and dissatisfied with social life in the capital, seeks freedom in the primitive beauty of the Caucasus, and in the simple life of its inhabitants, untainted by "civilization." Taken prisoner by the Circassians, and finally liberated by a Circassian girl who loves him, he is unable to respond to the passion of this "maid of the mountains" because at heart he is cold and prematurely aged; and she, in despair, throws herself into a mountain torrent and is drowned.

In the second poem of the cycle, *Bratya razboiniki* (1821–22; publ. 1827; *The Robber Brothers*), a work permeated with passionate thirst for freedom, and based on an event which took place during his stay at Yekaterinoslav, he describes the courageous escape from prison of two brothers, who, although chained and fettered, had swum across the Dnieper and got away.

Bakhchisaraiski Fontan (1821–23; publ. 1824; *The Fountain of Bakhchisarai*) is based on a legend. Girei, a warlike nomad, khan of the Crimea, conceives a deep and pure love for his captive, the Polish princess, Maria Potocka; but one of his wives murders her out of jealousy. In her memory, Girei erects a fountain (which Pushkin had seen in the khan's palace) surrounded by marble basins into which drops of water fall melodiously like tears.

"Evgeni Onegin."—Although this "southern" cycle of poems confirmed the reputation of the author of *Ruslan and Ludmila*, and Pushkin was hailed as the leading Russian poet of the day and as the leader of the romantic, liberty-loving generation of the 1820s, he himself was not satisfied with it. In May 1823 he started work on his central masterpiece, the novel in verse *Evgeni Onegin* (publ. 1833), on which he continued to work intermittently until 1831. In it, he returned to the idea (which had first found artistic expression in *The Prisoner of the Caucasus*) of presenting a typical figure of his own age, but in a wider setting and by means of new artistic methods and techniques.

Evgeni Onegin unfolds an encyclopaedically broad picture of Russian life in all its actuality. The characters it depicts and immortalizes—the disenchanted skeptic Onegin; the romantic, freedom-loving poet Lenski; and Tatyana, the heroine, a profoundly affectionate study of Russian womanhood: a "precious ideal," in the poet's own words—are typically Russian, and are shown in relationship to the social and environmental forces by which they are molded. Although formally the work bears a superficial resemblance to *Don Juan*, Pushkin rejects Byron's subjective, romanticized treatment in favour of objective description, and shows his hero not in exotic surroundings but at the heart of a Russian way of life. Thus, the action begins at St. Petersburg, continues on a provincial private estate, then switches to Moscow, and finally, in the last chapter, returns to St. Petersburg. This, the first Russian work to take as its subject contemporary society, points the way to the Russian realistic novel of the 19th century.

At Kishinev and Odessa.—Pushkin had meanwhile been transferred first to Kishinev (1820–23) and then to Odessa (1823–24). His bitterness at continued exile is expressed in letters to his friends—the first of a collection of correspondence which became an outstanding and enduring monument of Russian prose. At Kishinev, a remote outpost in Moldavia, he devoted much time to writing. Transferred to Odessa, "the Sodom of Bessarabia," he plunged into the life of a society engaged in amorous intrigue,

hard drinking, gaming, and violence. He made passionate love to the wife of his superior, Count Vorontsov, governor-general of the province. He fought several duels, and eventually the count asked for his discharge. Pushkin, in a letter to a friend, intercepted by the police, had stated that he was now taking "lessons in pure atheism." This finally led to his being again exiled, to his mother's estate of Mikhailovskoe, near Pskov, at the other end of Russia.

At Mikhailovskoe.—Although the two years at Mikhailovskoe were unhappy for Pushkin, they were to prove one of his most productive periods. Alone and isolated, he embarked on a close study of Russian history; he came to know the peasants on the estate, and interested himself in noting down folktales and songs. During this period the specifically Russian features of his poetry became steadily more marked. His ballad *Zhenikh* (1825; *The Bridegroom*), for instance, is based on motifs from Russian folklore, and its simple, swift-moving style, very different from the brilliant extravagance of *Ruslan and Ludmila* or the romantic, melodious music of the "southern" poems, emphasizes its stark tragedy.

In 1824 he completed *Tsygane* (publ. 1827; *The Gypsies*), begun earlier as part of the "southern cycle." In this, the most mature of his verse-romances, he puts into the mouth of an old gypsy, a representative of the people, a condemnation of the individual romantic hero, who wants freedom "only for himself." The style is dramatically harsh and spare, and the descriptive passages and dialogue are vigorous and realistic. At Mikhailovskoe, too, he wrote the provincial chapters of *Evgeni Onegin*; the poem, *Count Nulin* (1825; publ. 1828), based on the life of the rural gentry; and, finally, one of his major works, the historical tragedy, *Boris Godunov* (1824–25; publ. 1831).

"Boris Godunov."—This tragedy marks a break with the classicism of the French theatre, and is constructed on the "folk-principles" of Shakespeare's plays, especially the histories and tragedies, plays written "for the people" in the widest sense, and thus universal in their appeal. Written just before the Decembrist rising, it treats the burning question of the relations between the ruling classes, headed by the tsar, and the masses; it is the moral and political significance of the latter, "the judgment of the people," that Pushkin emphasizes. Set in Russia in a period of political and social chaos (c. 1595–1605), its theme is the tragic guilt and inexorable fate of a great hero—Boris Godunov, son-in-law of Malyuta Skuratov, a favourite of Ivan the Terrible, and here presented as the murderer of Ivan's little son, Dmitri. The development of the action on two planes, one political and historical, the other psychological, is masterly, and is set against a background of turbulent events and ruthless ambitions. The play owes much to Pushkin's reading of early Russian annals and chronicles, as well as to Shakespeare, who, as Pushkin said, was his master in bold, free treatment of character, simplicity, and truth to nature. Although lacking the heightened, poetic passion of Shakespeare's tragedies, *Boris* excels in the "convincingness of situation and naturalness of dialogue" at which Pushkin aimed, sometimes using conversational prose, sometimes a five-foot iambic line of great flexibility. The character of the pretender, the false Dmitri, is subtly and sympathetically drawn, and the power of the people, who eventually bring him to the throne, is so greatly emphasized that the play's publication was delayed by the censorship. Pushkin's ability to create psychological and dramatic unity, despite the episodic construction, and to heighten the dramatic tension by economy of language, detail, and characterization, make it one of his outstanding achievements, and a revolutionary event in the history of Russian drama.

Return from Exile.—After the suppression of the rising of Dec. 14 (O.S.), 1825, the new tsar, Nicholas I, aware of Pushkin's immense popularity, and knowing that he had taken no part in the Decembrist "conspiracy," allowed him to return to Moscow in the autumn of 1826. During a long conversation between them, the tsar met the poet's complaints about censorship with a promise that in the future he himself would be Pushkin's censor; and told him of his plans to introduce several pressing reforms from above, and, in particular, to prepare the way for liberation of the serfs.

The collapse of the rising had been a grievous experience for Pushkin, whose heart was wholly with the "guilty" Decembrists, five of whom had been executed, while others were exiled to forced labour in Siberia. Among them had been his closest friends at the Lyceum, I. I. Pushchin and the poet V. K. Kyuchelbeker (see the poem, "Arion"; and the epistle to Siberia, *Vo glubine sibirskikh rud* ["In the Depths of Siberia's Mines"], both written in 1827). Thus, when the tsar asked him outright how he would have acted, had he been in St. Petersburg on Dec. 14, he answered that he would have joined the ranks of the insurgents.

Pushkin saw, however, that the struggle against autocracy was doomed without the support of the people. He considered that the only possible way of achieving essential reforms was from above, "on the tsar's initiative," as he had written in *Derevnya*. This is the reason for his persistent interest in the age of reforms at the beginning of the 18th century, and in the figure of Peter the Great, the "tsar-educator," whose example he held up to the present tsar in the poem *Stansy* (1826; *Stanzas*); in *The Negro of Peter the Great* (1827; publ. 1837); in the historical poem *Poltava* (1828; publ. 1829); and in the poem *Medny Vsadnik* (1833; publ. 1837; *The Bronze Horseman*). In this last Pushkin poses the problem of the "little man" whose happiness is destroyed by the great leader, in pursuit of ambition, by telling a "story of St. Petersburg," set against the background of the flood of 1824, when the river took its revenge against Peter I's achievement in building the city. The poem describes how the "little hero," Evgeni, driven mad by the drowning of his sweetheart, wanders through the streets, and, seeing the bronze statue of Peter I, seated on a rearing horse, and realizing that the tsar, seen triumphing over the waves, is the cause of his grief, threatens him, and, in a climax of growing horror, is pursued through the streets by the "Bronze Horseman." Its descriptive and emotional power give it an unforgettable impact, and make it one of the greatest poems in Russian literature.

After returning from exile, Pushkin found himself in an awkward and invidious position. The tsar's censorship proved even more exacting than that of the official censors, and his personal freedom was curtailed. Not only was he put under secret observation from the police, but he was openly supervised by its chief, Count Benkendorf. When in 1829 during the Russo-Turkish War, after his applications to go to Transcaucasia had been refused, he managed to visit the front lines without permission, he was severely reprimanded by Count Benkendorf. This visit, on which he met several of the exiled Decembrists, is described in *Puteshestvie v Arzurum* (publ. 1836; *A Journey to Erzurum*).

Moreover, his works of this period met with little comprehension from the critics, and even some of his friends accused him of apostasy, forcing him to justify his political position in the poem *Druzyam* ("To my Friends," 1828). The anguish of his spiritual isolation at this time is reflected in the cycle of poems about the poet and the mob (1827-30); and in the unfinished *Egipetskie nochi* (publ. 1837; *Egyptian Nights*).

Yet it was during this period that Pushkin's genius came to its fullest flowering. His art acquired new dimensions, and almost every one of the works written between 1829 and 1834 opened a new chapter in the history of Russian literature. He spent the autumn of 1830 at his family's Nizhni-Novgorod (now Gorki) estate, and these months are the most remarkable in the whole of his artistic career. During them he wrote the four *malenkie tragedii* ("little tragedies"): *Skupoi rytsar* (1836; *The Covetous Knight*); *Kamennyi gost* (1839; *The Stone Guest*); *Pir vo vremya chumny* (1832; *Feast in Time of the Plague*); and *Mozart and Salieri* (1831); the five short prose tales collected as *Povesti Belkina* (1830; *Tales . . . by I. P. Belkin*); the comic poem of everyday lower-class life *Domik v Kolomne* (1830; *A Small House in Kolomna*); and many lyrics in widely differing styles; as well as several critical and polemical articles, rough drafts, sketches, etc.

One of Pushkin's most characteristic features was his wide knowledge of world literature, shown in particular by his interest in English literature from Shakespeare and Byron to Sir Walter Scott and the Lake poets; in Dostoevski's phrase, his "universal sensibility," his ability to re-create the spirit of different races

at different historical epochs without ever losing his own individuality. This is particularly marked in the "little tragedies," which are concerned with an analysis of the "evil passions," and, like *Pikovaya dama* (1834; *The Queen of Spades*), exerted a direct influence on the subject matter and techniques of the novels of Dostoevski; while his prose style paved the way for the prose of Turgenyev, Goncharov and Tolstoi.

Last Years.—In 1831 Pushkin, after a turbulent courtship and objections from her mother, married Natalya Nikolaevna Goncharova, and settled in St. Petersburg. Once more he took up government service, and was commissioned to write a history of Peter the Great. Three years later he received the rank of *Kammerjunker* (gentleman of the emperor's bedchamber) partly because the tsar wished Natalya to have the *entrée* to court functions. The social life at court which he was now obliged to lead, and which his wife enjoyed, was ill-suited to creative work, but he stubbornly continued to write. Without abandoning poetry altogether (the fairy tales in verse, *Skazki*, belong to this period, as well as *The Bronze Horseman*), he turned increasingly to prose. Alongside the theme of Peter the Great, the motif of a popular peasant rising acquired growing importance in his work, as is shown by the unfinished satirical *Istoriya sela Goryukhina* (1830; publ. 1857; *History of the Village of Goryukhino*); the novel *Dubrovski* (1832-1833; publ. 1841); *Stseny iz rytsarskikh vremen* (1835; dramatic *Scenes from the Age of Chivalry*); and finally, the most important of his prose works, the historical novel of the Pugachev Rebellion, *Kapitanskaya dochka* (1833-36; publ. 1836; *The Captain's Daughter*), which had been preceded by a historical study of the rebellion (1834; publ. 1835).

Meanwhile, both in his domestic affairs and in his official duties, his life was becoming more intolerable. In court circles he was regarded with mounting suspicion and resentment, and his repeated petitions to be allowed to resign his post, retire to the country, and devote himself entirely to literature, were all rejected. Finally, on Feb. 8, 1837, in a duel forced on him by influential enemies, defending his wife's honour, Pushkin fell, mortally wounded. His adversary, Georges d'Anthès, an officer in the guards and the adopted son of the Dutch ambassador, Baron Heeckeren, had emigrated from France after the revolution of 1830, and was the husband of Natalya's sister. Pushkin died of his wounds at St. Petersburg, on Feb. 10 (N.S.; Jan. 29, O.S.), 1837.

Critical Assessment.—Even during his lifetime, Pushkin's importance as a great national poet had been recognized by N. V. Gogol (q.v.), his successor and pupil; and it was his younger contemporary, the great Russian critic, democrat, and revolutionary, V. Belinski (q.v.), who produced the fullest and deepest critical study of Pushkin's work, which still retains much of its relevance. To the later classical writers of the 19th century, Pushkin, the creator of the Russian literary language, the author of the standard works of Russian literature, the "poet of reality" (as he said of himself), stands as the cornerstone of Russian literature; in Gorki's words "the beginning of beginnings."

Pushkin has become an inseparable part of the cultural and spiritual world of the Russian people and of the other peoples of the former tsarist empire to whom he bequeathed his work (in the poem *Ya pamyatnik vozdrig* [*Exegi monumentum*], 1836). He has exerted, too, a profound influence on other aspects of Russian culture; most notably, in opera (q.v.).

Today, Pushkin's work, with its nobility of conception and its emphasis on civic responsibility (shown in his command to the poet-prophet to "fire the hearts of men with his words"), its life-affirming vigour, its confidence in the triumph of reason over prejudice, of light over darkness, of human charity over slavery and oppression, has struck an echo all over the world, and his works, translated into all the major languages, are regarded as both the most complete expression of the Russian national consciousness and as transcending national barriers by their power and inspiration.

BIBLIOGRAPHY.—*Editions, etc.*: The best Russian editions of Pushkin's complete works are *Polnoe sobranie sochineni*, 16 vol. (1937-49), reference vol. (1959); and *Polnoe sobranie sochineni*, 10 vol. (1956-59).

58), both edited and published by the Academy of Sciences of the U.S.S.R. Bibliographies include V. I. Mezhev, *Puschkiniiana* (1886); A. G. Fomin, *Puschkiniiana, 1900–10* (1929), 1911–17 (1937); A. M. Dobrovolski and N. I. Mordovchenko, *Bibliografiya proizvedeni Pushkina i literaturny o nem, 1918–36* (1952); and bibliographies for 1949 (the 150th anniversary year) (1951), 1950 (1952), and 1954–57 (1958), all published by the Academy of Sciences of the U.S.S.R.

Editions of separate works include *Kapitanskaya dochka*, with introduction and notes, by Anna H. Semeonoff (1937); *Pikovaya dama*, by D. Bondar, 3rd ed. (1943); *Povesti Belkina*, by B. O. Unbegaun (1947); *Boris Godunov*, with Eng. trans. and notes by Philip L. Barbour (1953); *Evgeni Onegin*, with introduction and commentary by D. Cizevsky (1953). See also N. L. PUSHKIN (formerly TSARSKOE SELO), a town of Leningrad oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies 15 mi. S of Leningrad on the railway to Novgorod. Administratively the town comes under Leningrad City Council. Pop. (1959) 46,000. Tsarskoe Selo ("the Tsar's village") grew up around one of the main summer palaces of the Russian royal family. The land was given by Peter the Great to the tsaritsa Catherine I. in the distribution of Ingrian lands after the success of Peter's campaigns of 1702–04. Catherine built first a wooden palace (1712–14) and then a stone palace (1718–24), designed by the architect I. F. Braunshtein. The present palace was designed by V. V. Rastrelli for the tsaritsa Elizabeth and built between 1748 and 1762. The building is imposing and amply proportioned. The superb facade is 220 yd. in length. The palace and its surrounding park, also laid out by Rastrelli, were both considerably embellished under Catherine the Great by the Scots architect Charles Cameron, who redesigned 18 state rooms and constructed a fine gallery overlooking the lake and park. During World War II the palace was deliberately gutted by the Germans, only the Cameron Gallery surviving intact. After the war restoration was begun and by the early 1960s the fabric and most of the Cameron state rooms had been scrupulously restored and work was proceeding. In the magnificent "English" park round the palace is the smaller Alexander Palace, built by Giacomo Quarenghi in 1792–96 for Catherine the Great; it was also gravely damaged but has been restored. In the park also are many pavilions, statues, and monuments, including the Hermitage, designed by Rastrelli, and the Agate pavilion of Cameron. These two buildings survived the

war. Cameron also designed the rococo Chinese village, now mostly in ruins. On the lake side is a neo-Gothic boathouse, known as the Admiralty, and on an island in the lake is the Orlov column, commemorating the victory of Aleksei Orlov over the Turks at Cheshme (Cesme). Immediately adjacent to the main palace is the *Lycée*, now converted to a museum in honour of the Russian poet Aleksandr Pushkin, who studied at the *Lycée* from 1811 to 1817. Also in the poet's honour, the town was renamed in 1937, after having first been renamed Detskoe Selo ("children's village"). The first railway in the Russian Empire was built in 1837 from St. Petersburg (Leningrad) to Tsarskoe Selo. The Leningrad Agricultural Institute is in the modern town.

About 5 mi. S of Pushkin is Pavlovsk, with another royal palace and surrounding park, designed by Cameron in 1782. The palace was burned down in 1803, but carefully restored. Destroyed a second time by the Germans in World War II, it has again been rebuilt. The park, almost as fine as that of Pushkin, has many pavilions of the late 18th and early 19th centuries. (R. A. F.)

PUSHTU: see PASHTO.

PUT AND CALL. A "put" in stock market parlance is a contract which gives the put holder an option to sell or put shares to the other party at a fixed put price even though the market price declines; a call, on the other hand, gives the holder an option to buy or call for shares at a fixed call price notwithstanding a market rise. See **OPTION (STOCK)**. (G. T. FR.)

PUTA-O, the largest of three districts of the Kachin state (q.v.) of the Union of Burma and also the name of its chief centre. The district occupies the sparsely inhabited forested country in the extreme north of Burma and stretches to the borders of India, Tibet, and China. Burmese maps, following Survey of India maps, show the whole or nearly the whole of the basin of the Irrawaddy headwaters within Puta-O and the water parting as the political frontier. The boundary has never been fully demarcated and is not accepted by the Chinese. Virtually the whole district is forested; a little shifting cultivation is practised by the Kachins (see **KACHIN**).

Puta-O town, formerly Fort Hertz, is reached by an old mule track from the railhead at Myitkyina to the south. The Stilwell Road, constructed by U.S. forces in World War II, enters Kachin state west of this area, through the Hukawng Valley. (L. D. S.)

PUTEAUX, a suburb of Paris in Hauts-de-Seine département, France, is on the left bank of the Seine opposite the Bois de Boulogne, 5½ mi. (9 km.) W of Notre Dame by road. Pop. (1962) 39,640. It has one of the finest town halls in France, which gained the Prix Bailly in 1934. On the island in the Seine are a stadium, with facilities for many sports, and a swimming pool. There is a national exhibition centre, a national industrial and technical centre, and a technical *lycée*. Puteaux was the cradle of the French automobile industry. Trucks, electric locomotives, electrical equipment, aircraft, rubber goods, and perfumes are manufactured. Puteaux was known to the Romans as Puteoli (little wells). Before its industrial development it was a village noted for rose and vine cultivation. A principal street is named after Sir Richard Wallace (q.v.; d. 1890 in Paris), the art collector and philanthropist, who was a benefactor of Puteaux. (AL. SC.)

PUTEOLI: see POZZUOLI.

PUTNAM, RUFUS (1738–1824), American soldier in the Revolutionary War and pioneer settler in Ohio, was born in Sutton, Mass., on April 9, 1738 (old style). He served in the French and Indian War in 1757–60; was a millwright in New Braintree in 1761–68, during which time he studied surveying; and from 1769 until the outbreak of the American Revolution was a farmer and surveyor. He became lieutenant colonel in one of the first regiments raised after the battle of Lexington and served before Boston. In 1777 he served in the Northern army under Gen. Horatio Gates, commanding two regiments in the second battle of Saratoga. In 1778 he laid out fortifications, including Ft. Putnam, at West Point, and in 1779 he served under Gen. Anthony Wayne after the capture of Stony Point.

After the war he returned to Rutland, Mass., where he had bought a confiscated farm in 1780. In March 1786 he founded, with other officers of the American Revolution, the Ohio Company

of Associates for the purchase and settlement of western lands (see OHIO COMPANY). In Nov. 1787 he was appointed by the company superintendent of its proposed settlement on the Ohio, and in 1788 he led the small party which founded Marietta, Ohio. Putnam was appointed territorial judge, a brigadier general in the regular army and a commissioner to treat with the Indians in 1792-93; was surveyor general of the United States in 1796-1803; and in 1802 was a member of the Ohio state constitutional convention. He died in Marietta, May 4, 1824.

See Rowena Buell (ed.), *The Memoirs of Rufus Putnam* (1903), in which his autobiography, journal and other papers, in the library of Marietta college, are reprinted. His *Journal, 1757-1760*, dealing with his experiences in the French and Indian War, was edited with notes by E. C. Dawes (1886).

PUTNIK, RADOMIR (1847-1917), Serbian army officer, a victorious commander against the Austrians in 1914, was born at Kragujevac on Jan. 24 (new style), 1847, the son of a teacher. Educated at the artillery school, he was commissioned in 1866. He graduated from the staff college in 1889 and rose to be general in 1903. Save for three periods when he was war minister (1904-05, 1906-08, 1912), he served as chief of staff from 1903 to 1916. It was he who was mainly responsible for the professional skill, good equipment, and fighting spirit of the Serbian army.

Putnik headed a brigade in the two wars against Turkey (1876, 1877-78) and the staff of a division in the war against Bulgaria (1885). He was commander in chief in the two Balkan Wars (1912-13), routing the Turks at Kumanovo (October 1912) and—as field marshal—at Monastir (Bitola; November 1912). Largely because of him, the treacherous Bulgarian night attack failed and the Bulgars were defeated at Bregalnica (June-July 1913). When World War I began, Putnik, who was at Gleichenberg in Austria, was escorted to Rumania. In poor health, he resumed the command in chief and routed the overwhelming Austrian forces of Gen. Oskar von Potiorek on Tser Mountain (August 1914; the first Allied victory in the war) and on the Kolubara River (November-December 1914). During the retreat across Albania a year later, Putnik, carried in a sedan chair, shared the fate of his army. After the retreat, he was relieved of his command and withdrew to Nice, where he died on May 17, 1917. (K. St. P.)

PUTTENHAM, GEORGE (c. 1529-1590), English courtier, generally acknowledged as the author of the anonymously published *The Arte of English Poesie* (1589), one of the most important critical works of the Elizabethan age.

Little is definitely known of his early life. His mother was the sister of Sir Thomas Elyot (*q.v.*), his sister married Sir John Throckmorton, and by his own marriage (c. 1560) to Lady Elizabeth Windsor he was connected with other wealthy and influential families. Perhaps educated abroad, he visited Flanders and other countries between 1563 and 1578. He had matriculated at Cambridge in 1546 and was admitted to the Inner Temple in 1556. Throckmorton paid his debts, rescued him from prison in 1569 when he was charged with conspiring to murder the Calvinist bishop of London, and in 1570, when he criticized the queen's counselors too freely, and supported him during his long financial wrangle with his wife's family, standing surety for him at its conclusion in 1579. His knowledge of law and public affairs is shown by *A Justificacion of Queen Elizabeth in Relation to the Affair of Mary Queen of Scottes*, undertaken at the queen's request and anonymously circulated, but attributed to Puttenham in two of eight extant copies of the manuscript (British Museum, Harleian MS. 831; Calthorpe MS.). He was rewarded for "good, true, faithful and acceptable service" to the queen in 1588. He died in London in the autumn of 1590.

George Puttenham's authorship of *The Arte of English Poesie*, early attributed to him but later disputed in favour of his brother, Richard, and of Lord Lumley, is supported by comparison of the style and opinions in it, in *Partheniades* (a collection of poems addressed as a New Year's gift to the queen, probably in 1581-82), and in the *Justificacion*; and also of the known facts of Puttenham's life and abilities with those revealed in the *Arte*.

The *Arte* is divided into three books: I, "Of Poets and Poesy," defending and defining poetry; II, "Of Proportion," dealing mainly with prosody as an indispensable formal element of the art

of poesy; and III, "Of Ornament," defined as all that renders poetic utterance attractive to eye and ear. Its importance lies in its treatment of English poetry as an art, at a period when this was still disputed; in its appeal to "right reason" as the best judge of poetry and the poetic technique; and in its emphasis on the creative, imitative, and "image-forming" faculties of the poet, and on poetry's primary purpose as giving pleasure rather than instruction. In its treatment of English prosody, and of poetic kinds as including those popular in England, and in its critical estimate of English poetry from Chaucer to Wyatt and Surrey, it is a pioneer work. It reveals an original, enquiring mind, and a concern to "fashion an art of poesie" which should be perfected by the poets of the future. Its loosely constructed, digressive prose-style is enlivened by anecdote and quotation, for Puttenham wrote for a courtly audience and sought to avoid "scholarly preciosities." His work shows that he had read widely and had interpreted what he read by the critical faculty provided by Nature rather than by the rules of classical rhetoric.

Jones, *The Triumph of the English Language* (1953).

PUTTING THE SHOT: see SHOT-PUT.

PUTTY, a term that generally means a cement of one of two types: whiting putty or white-lead whiting putty. A high-grade whiting putty consists of 85% to 90% whiting (finely powdered calcium carbonate) blended with 10% to 15% boiled linseed oil. White-lead whiting putty has an admixture of 10% white lead, reducing the amount of whiting proportionately. Prepared putty should roll freely in the hands without exuding oil. It is commonly used to secure sheets of glass in place, to fill nail holes, etc.

The term is also applied to substances resembling putty, for example, iron putty, which is a mixture of ferric oxide and linseed oil, and red-lead putty, which is composed of red and white lead and linseed oil. The term putty is also applied to certain dough-like plastic compounds. Putty is also a shortened name for putty powder (tin oxide), which is used in polishing glass, granite, metal, etc. (E. L. Y.)

PUTUMAYO RIVER, a 980 mi.-long tributary of the Amazon which rises in the Andes mountains of southern Colombia, forms the southern boundary of Colombia with Ecuador and Brazil for almost 800 mi., but for its last 100 mi. before it enters the Solimões or Amazon at Santo Antonio de Içá it flows through Brazilian territory. In Brazil it is known as the Içá river.

The area drained by the Putumayo is a vast zone of tropical rain forest where rainfall ranges upward to 140 in. a year. Except near its headwaters, in the foothills of the Andes, the population along its banks is composed largely of small groups of forest Indians.

A highway built by the Colombian government from Pasto through the Sibundoy valley to Puerto Asís on the upper Putumayo was opening the eastern flanks of the Andes to settlement in the second half of the 20th century. Another road was under construction from Ipiales toward the valley of the Rio San Miguel, which is a main affluent of the Putumayo and itself forms the Ecuador-Colombian border near its headwaters. Navigation on the Putumayo is unobstructed by rapids below Puerto Ospina, 80 mi. downstream from Puerto Asís. The only settlement of any size on the Putumayo below Puerto Ospina is Puerto Leguizamo (formerly Caucayá), from which there is a 25 mi. portage road northward to La Tagua on the Caquetá river.

The Putumayo region was the scene of the famous Putumayo rubber scandal during the height of the rubber boom which saw many Indians enslaved and killed by unscrupulous rubber operators. In 1932 there was fighting there between Colombian and Peruvian forces prior to the settlement of the so-called Leticia affair, which gave Colombia a wedge-shaped salient that extends 90 mi. south of the Putumayo to the Amazon port of Leticia. (Js. J. P.)

PUVIS DE CHAVANNES, PIERRE CÉCILE (1824-1898), French painter, was born at Lyons on Dec. 14, 1824. He

"THE POOR FISHERMAN" BY PUVIS DE CHAVANNES, 1881. IN THE LUXEMBOURG PALACE, PARIS

occupied a rather unique position in 19th-century painting, for his work was largely independent of the major artistic currents and, perhaps for that very reason, it was approved by representatives of almost all shades of critical opinion. The son of a mining engineer, Pierre Puvis was educated at Lyons and at the Lycée Henri IV in Paris and was intended to follow his father's profession.

Puvis first studied painting under Henri Scheffer, spent some time in Italy and then frequented for a short period the studios of Thomas Couture and Eugène Delacroix. He first exhibited at the Salon in 1850 (a *Pietà*), but was then consistently rejected until 1858. His work was, however, esteemed by such critics as Théodore de Banville, Théophile Gautier, Charles Baudelaire and Paul de St. Victor. In 1859 he reappeared at the Salon with the "Return from Hunting" (Marseilles), an adaptation of a "Return of the Prodigal Son" executed in 1854 as part of a decorative scheme for his brother's dining room. In 1861, with the production of "War" and "Peace," he began an important series of paintings which were destined to become part of the decorative scheme for the museum at Amiens. The scheme was augmented by various gifts from the artist and finally completed with "Ave Picardia Nutrix" (1865) and the state commission for "Pro Patria Lulus" (1882).

During these years Puvis de Chavannes undertook other decorative work at Lyons, Marseilles, Poitiers and Paris, as well as exhibiting a number of important pictures such as the "Beheading of St. John" (1869), "Hope" (1872), "Family of Fisher-folk" (1875), "Women on the Seashore" (1879) and "The Poor Fisherman" (1881). The work at Lyons includes "Autumn" (Salon of 1864) and the major decorative works "The Sacred Grove," "Vision of the Antique," "The Rhône" and "The Saône" (1884-87).

In the Palais Longchamp at Marseilles are two panels representing "Marseilles as a Greek Colony" and "Marseilles, Gateway to the East" (1868-69) and in the Hôtel de Ville, Poitiers, are two decorative panels of historical subjects, "Radegund" and "Charles Martel" (1872-74). In 1876 Puvis de Chavannes was commissioned to paint a series of panels illustrating the life of St. Genevieve, for the Panthéon; although part of this task was finished and exhibited by 1880, the total scheme was completed only after the death of Puvis in Paris (Oct. 24, 1898) by pupils, under the direction of J. C. Cazin, working from the completed cartoons. Other mural decorations in Paris are those for the Sorbonne (1887-89, and for the Hôtel de Ville, which were completed in 1893. Two other important decorative commissions were those for the museum at Rouen (1890-92) and for the staircase of the public library, Boston (1894-98).

et la peinture lyonnaise du XIXe siècle (exhibition catalogue, 1937); R. Goldwater, *Art Bulletin* (1946). (R. A. Dv.)

PUY, LE, a town of southern France, *préfecture* of Haute-Loire *département* and former capital of Velay, is situated 56 km. (90 mi.) S.W. of Lyons in the Massif Central at slightly more than 2,000 ft. above sea level. Pop. (1962) 22,396. It lies in the middle of a basin surrounded by basalt plateaus. The basin, crossed by the upper course of the Loire river, has an infilling of soft marls and sands, but is studded with residual volcanic hills (*puys*). In this highland setting it is a relatively rich farming district and was the nucleus of the tribal territory of the Vellaves (whence Velay) in Roman Gaul, although their capital was then at St. Paulien (Reversio) about 8 mi. N. of Le Puy. During the barbarian invasions, about A.D. 500, the capital was shifted to the defensive site that was provided by a steep volcanic hill, the Rocher Corneille (Mont Anis). The bishopric was moved there and a shrine was established to the Virgin. From the 10th century it was an important centre of pilgrimage, known as Podium Sanctae Mariae. The Romanesque cathedral (Basilique de Notre-Dame du Puy), dating from the 12th century and built on a platform beneath the summit of the Rocher Corneille, is reached through the old town, whose narrow, steep streets occupy the mountain-side. A great flight of steps leads up to the façade of the cathedral.

Parts of the old town walls are preserved, and beyond the boulevards that mark their line downhill the modern town has grown with squares, wide streets, public buildings and a railway station. On the outskirts another volcanic peak, Rocher d'Aiguilhe, in the form of a natural obelisk is crowned by the 11th-century church of St. Michel d'Aiguilhe, reached by 271 steps. About three miles away, the massive square keep and ruins of the medieval castle of Polignac occupy a tabular fragment of basalt. A magnificent panorama of this bizarre landscape, bristling with volcanic hills, is commanded by the colossal statue (53 ft. high) of Our Lady of France, set up in 1860 on the summit of the Rocher Corneille at Le Puy, more than 300 ft. above the surrounding plain.

The administrative, market, and general service centre of Velay, Le Puy is also closely associated with the rural life of its surrounding district by the lace industry, which grew from the decoration of religious objects and became very prosperous in the 17th and 18th centuries. Changes of fashion have adversely affected the general prosperity of the industry, and handmaking of lace has especially declined. The Crozatier museum at Le Puy houses a notably fine collection of lace. (AR. E. S.)

PUY-DE-DÔME, a *département* of central France formed in 1790 mainly from Auvergne (*q.v.*), with the addition of adjacent districts of Bourbonnais and Lyonnais. It is bounded north by Allier, east by Loire, south by Haute Loire and Cantal, west by Corrèze and Creuse, and consists of very diverse physical regions in the heart of the Massif Central. Area, 3,095 sq.mi. (8,016 sq.km.). Pop. (1962) 505,928.

Puy-de-Dôme is crossed from south to north by the Allier River, which occupies a downfaulted trough, floored with young sediments, between the highlands of Auvergne and Forez. In the south, by Issoire, the plain, known as the Limagne, is narrow and much encumbered with residual hills, but toward Clermont-Ferrand it widens out. To the west a line of young volcanic cones, the Chaîne des Puys, surmounts the edge of the granite plateau of Auvergne and dominates the Limagne above its sharp fault-line margin. Chief among them is the Puy de Dôme (4,806 ft. [1,465 m.]) above Clermont-Ferrand. Farther west the Sioule River drains the granite plateau north toward the Allier. In the south-west part of the *département* the Mont Dore is another volcanic mass, with four major centres of eruption, culminating in the Puy de Sancy (6,188 ft. [1,886 m.]). The volcanoes were active in Quaternary times and fresh volcanic landforms remain, including extensive rocky wildernesses of ash and lava. In the volcanic areas small lakes occupy crater hollows or valleys blocked by lava dams and there are several important thermal springs, notably at Châtel Guyon, Royat, La Bourboule, Mont Dore, and Saint-Nectaire. East of Limagne the granite Forez Highlands, exceeding 5,000 ft. (1,500 m.), separate the basins of the Allier and Loire.

They are cut into by the Dore River, connecting the small, high-lying tectonic basin of Ambert with the Limagne by the gorges of Olliergues.

In contrast with the wet, severe climate of the surrounding highlands, the low-lying and sheltered Limagne is dry and warm, and is occupied by an extension of lowland agriculture. The soils in the west, derived from volcanic rocks, are especially rich, though rather heavy. The damp strip along the Allier, known as Le Marais, especially required costly drainage to realize its present productivity. Farther east the soils derived from the granitic Forez are poorer and gravelly. The plain is predominantly arable and wheat is extensively grown, though grain has lost ground to fodder crops. Hemp, which was once important, has greatly decreased, but potatoes and sugarbeets have become important. The vine has failed to recover much of the area it lost during the phylloxera trouble of the late 19th century. Orchards and market gardens are especially prominent and supply important preserving industries. There is a heavy density of livestock, with pig- and poultry-keeping on small holdings a specially developed feature. There are important lines of villages and market towns at the foot of the bounding highlands, and residual hills in the plain are often crowned by ruins of castles, with villages clustered below.

The flanking highlands are areas of poor farming, largely pastoral, with seasonal use of the highest pastures, which are snow-covered in winter. The pivot of the local economy is the *buron* (dairy), where cheese is made. These districts have suffered severe depopulation since the mid-19th century, as their inhabitants have been drawn away to urban employment at Clermont-Ferrand and farther afield. Clermont, with a great rubber industry, has grown rapidly as an industrial centre. Manufacture of clothing, food preserving, and other industries, e.g., the production of fertilizers, associated with the agriculture of the Limagne, are also important. Clermont is provided with hydroelectric power from the Sioule River and, elsewhere, hydroelectric power has been developed and has replaced the direct use of falling water in the industrial communities on the Dore below Ambert (paper, textiles, rosaries) and at Thiers on the Durolle, where there is a long-established cutlery industry. In the Allier Valley, both in the extreme north and south of the *département*, a little coal is mined at Brassac and Saint-Éloy. There are large quarries in the lava at Volvic, and asphalt is worked at Pont du Château. Among the spa towns, Mont Dore is now developing as a centre of winter sports on the Puy de Sancy.

Clermont-Ferrand (*q.v.*), the regional capital for an extensive area, is the *préfecture* of the *département*, the centre of a bishopric, and the headquarters of educational administration, but the court of appeal remains at the old legal centre of Riom, the scene of trials at the end of World War II. Clermont-Ferrand, Riom, Ambert, Thiers, and Issoire are the centres of the five *arrondissements* into which the *département* is divided. Gergovia, on a basal table eight miles south of Clermont, was the scene of Vercingetorix' repulse of Julius Caesar during the Roman conquest of Gaul. Among many churches that exemplify the Auvergnat style of Romanesque architecture, those at Issoire, Riom, and Saint-Nectaire deserve special mention. (AR. E. S.)

P'U YI, HENRY: see HSÜAN-T'UNG.

PWLLHELI ("salt water pool"), a municipal borough, former seaport, and market town of Caernarvonshire, north Wales, lies 21 mi. SSW of Caernarvon by road on the northern shores of Cardigan Bay. Pop. (1961) 3,642. It consists of an old town (incorporated in 1355 by Edward the Black Prince) and two seaside suburbs known as South Beach and West End. Its economic activities are dependent on its agricultural hinterland and the tourist trade.

(E. G. Bow.)

PYANOPSIA, an ancient festival in honour of Apollo, held at Athens on the 7th of the month Pyanopsion (October). A hodgepodge of pulse was offered to Apollo. Another offering was a branch of olive or laurel, bound with purple or white wool, round which were hung fruits of the season, pastries, and small jars of honey, oil, and wine. Both are old pieces of rustic magic, for which many analogies can be found elsewhere. The offerings were carried in procession to the temple of Apollo where they were suspended

on the gate by a boy whose parents were both alive. The doors of private houses were similarly adorned. The branch was allowed to hang for a year, when it was replaced by a new one, since by that time it was supposed to have lost its virtue. During the procession a chant was sung, the text of which has been preserved in Plutarch's *Theseus*.

Both offerings have been connected with the Cretan expedition of Theseus, who, when driven ashore at Delos, vowed a thank-offering to Apollo if he slew the Minotaur; the offering afterward took the form of the olive or laurel branch and Pyanopsia. His comrades on landing in Attica gathered up the scraps of their provisions which explains the origin of the hodgepodge.

PYAPON, a town and district in the Irrawaddy Delta of Burma. The district, with an area of 2,136 sq.mi. (5,532 sq.km.) and a population (1962 est.) of 518,377, was formed in 1903 when the reclamation of the alluvial marshlands for paddy cultivation had attracted a large number of settlers, both Burmans and Karens. It has no railways and few roads, communication being by water. The district headquarters, Pyapon (pop. [1953] 19,174), lies on the Pyapon River, one of the delta distributaries, 45 mi. (72 km.) SW of Rangoon. It ships rice by delta creeks to Rangoon as do the other centres Kyaiklat and Dedaye. During the Japanese occupation in World War II and subsequent disturbances the paddy trade was disrupted, large areas were abandoned, and cultivators became refugees. (L. D. S.)

PYAT, FELIX (1810–1889), French journalist, dramatist, republican deputy, and Commune, was born at Vierzon, Cher, on Oct. 4, 1810. After studying for the bar, he became a journalist and took part in the political struggles of the 1830s. His polemics involved him in many legal actions. Sued by Jules Janin, whom he had ridiculed in a pamphlet (1844), he was imprisoned for six months. He later contributed articles to *Le Siècle*, *Le National*, and *La Réforme*, in which he attacked the Romantic movement as reactionary. He was already writing plays and became a friend of George Sand, through whose influence he was appointed *commissaire-général* of the Cher *département* by A. A. Ledru-Rollin after the Revolution of 1848. After three months in office, he was returned by the Cher to the Constituent Assembly, where he proposed the abolition of the presidency and was a champion of workers' rights. Having inherited a fortune from his father, Pyat was mistrusted by many fellow socialists and fought a duel with Pierre Proudhon, who had called him "l'aristocrate de la démocratie." A member of the Legislative Assembly, he joined Ledru-Rollin in the rising on June 13, 1849. Then he took refuge abroad. He returned to France in 1869, but made further outbursts against the government and had to flee again. The fall of the Second Empire enabled him to return to Paris, where he was imprisoned for a short time after the insurrection of Oct. 31, 1870. His paper, *Le Combat*, was suppressed in January 1871, to be replaced by *Le Vengeur*. Elected to the National Assembly in February 1871, Pyat refused to vote for peace with Germany and was elected to the Commune (*q.v.*) of Paris in March. He managed to escape the repression following the fall of the Commune and fled to England in 1872. Though he had been condemned to death in his absence in 1873, he could return to France after the amnesty of 1880. Elected a deputy for Bouches-du-Rhône in March 1888, Pyat died at Saint-Gratien on Aug. 3, 1889. His publications include: *Une Conjuración d'autrefois* (1833), *Discours aux paysans* (1849), *Lettres d'un proscrit*, two volumes (1851), and *La Folle d'Ostende* (1886).

PYATIGORSK, a town of Stavropol *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Podkumok River, a headstream of the Kuma, in the northern foothills of the Caucasus, at the foot of Mt. Mashuk. Pop. (1959) 69,617. The town is the centre of a region of abundant mineral springs and is a popular health resort. The waters of Pyatigorsk contain carbon dioxide, hydrogen sulfide, and radioactive gases reputedly good for rheumatic, bone, nervous, and intestinal complaints. There are 15 sanatoriums and a number of therapeutic baths and physiotherapeutic establishments. The town has many associations with the poet M. Y. Lermontov, who was killed in a duel there in 1841. (R. A. F.)

PYCNOGONIDA (SEA SPIDERS) are spiderlike marine animals which occur in all oceans, especially the arctic and antarctic, usually as bottom dwellers. Also called Pantopoda and rarely, Podosomata, they comprise a subphylum or a class of the phylum Arthropoda (*q.v.*) and resemble spiders (arachnids) in having the first pair of appendages characteristically arachnidlike or chelicerate. In most other respects pycnogonids are distinct from all other groups of arthropods. They are characterized by a relatively small body, excessively long legs with a patellar segment, and an additional pair of legs (ovigers) used by the male to carry the eggs about in a compact ball. The ovigers are present in all males except one New Zealand species but are lacking in the females of several genera. The sexes are usually separate, but one hermaphroditic species from Brazil has been described. Most species have eight walking legs, but species with ten legs are not uncommon in antarctic and Caribbean regions, and there is a 12-legged one in the antarctic. In addition to the walking legs and ovigers there may be a pair of pincerlike or chelate appendages (chelifores) and sensory palpi; the presence or absence of these appendages constitutes the basis of classification within the group, which includes about 50 genera divided into eight or nine families.

A PROTONYPHON LARVA

The body of a pycnogonid consists of a cephalic segment or head region, followed by three to five trunk somites, which may be either distinctly segmented or coalesced into a compact disc, and a usually small, fingerlike abdomen with the anus at the tip. The mouth is a triangular opening at the end of an elaborate suctorial appendage (proboscis) which is often much longer and larger than the body. In such pycnogonids as *Nymphon* or *Achelia* the cephalic segment bears three pairs of appendages anterior to and in addition to the first pair of legs, the chelifores, which may or may not be chelate; the palpi, usually flanking the proboscis; and the ovigers, originating on the ventral surface. The extreme of reduction is found in *Pycnogonum*, which lacks both chelifores and palpi and has ovigers only in the males (except one species which has none). There are usually four simple eyes, located in a tubercle or elaborate process on the dorsal surface of the cephalic segment, but eyes are often lacking in deep-sea species. The digestive and reproductive systems have branches into the legs. The genital openings are usually on the ventral surface of the second joints of the last pair of legs but occur occasionally on all legs; the sexual products are stored in the fourth or femoral joints of the legs. The circulatory system is a simple dorsal heart with two or three pairs of lateral slits (ostia). The nervous system is composed of a supra-esophageal brain or ganglion and a chain of five or six ventral ganglia. There is no specialized excretory or respiratory system; secretory or cement glands occur in the males on the legs; and some species have a blood pigment of uncertain nature.

In all species of which the habits are known, the male attaches the eggs to his ovigers in masses or clusters as they are extruded from the female and carries them with him till they hatch into larvae. In some species the young larvae become attached to hydroids or polyps, in which they form galls or cysts; others are known to invade the medusa or jellyfish stage. The larval stages of a Japanese species, *Nymphonella tapetis*, are parasitic in the mantle cavity of clams; similar infestation of mussels by a California species has been observed. Others are associated with sea slugs (nudibranchs) and one may live within a sea cucumber (holothurian). Most species, however, are associated with coelenterates. The life cycle of deep sea forms, especially members of the genus *Colossendeis*, is unknown.

Pycnogonids occur in all oceans from the littoral zone to depths of more than 2,000 fathoms (12,000 ft.) but are especially abundant in arctic and antarctic waters. Most species are bottom dwellers, feeding on the soft parts and body juices of coelenterates

and other defenseless animals, but some live on the floating *Sargassum* in the mid-Atlantic; one, *Pallenopsis calcaranea*, is bathypelagic, living at depths of 1,200–2,000 m. (about 4,000–6,500 ft.) in the Atlantic and Pacific oceans. Some species ascend to the surface to breed, swimming by treading water with their long legs. In size pycnogonids range from a spread of 3 to 4 mm. in such forms as the littoral *Tanystylum* to about 50 cm. in deep sea species of *Colossendeis*. While pycnogonids may sometimes occur in massive numbers, they are of no commercial significance and their study is untinged by economic motives.

One Devonian fossil, without discernible anterior appendages or proboscis, is considered to represent an extinct order, Paleopantopoda, while all the living species are included in the order Pantopoda. The Pycnogonida cannot be associated with the Arachnida because the sexual apertures are not restricted to the second abdominal somite (there being no such segment) as in Arachnida; the multiple gonopores are a condition not found in other living arthropods. Nor can they be considered as allied to Crustacea because they do not have antennae or biramous appendages at any stage. The patellar segment of the leg is an arachnid character, and the occurrence of both flexor and extensor muscles in the distal joint of the leg is a character of Crustacea as well as Arachnida. The musculature of the oviger is unique among arthropods: the distal division or tarsal segments are individually muscled. The chelate protonymphon larva is unique. The occurrence of supernumerary legs is not comparable with similar phenomena in other groups but seems instead to be a sort of polymorphism, possibly within a species, although the forms have been given generic names.

PYDNA, BATTLE OF (June 22, 168 B.C.), the engagement that brought victory to Rome in the Third Macedonian War. In 168 the Romans sent out an efficient general, Lucius Aemilius Paulus. Finding Perseus, the Macedonian king, in an impregnable position on the Elpeus (Mavrolongos) River, Paulus sent a detachment round the Olympus Range and forced him to fall back to a weaker position in the plain south of Pydna (modern Kitros; the actual site was probably near modern Katerini). Perseus now faced the risk that Paulus could penetrate into Macedonia while another Roman army from Illyria might converge from the north: he must fight.

On June 22 the two armies were drawn up for battle on either side of a stream. Throughout the morning Perseus failed to induce the Romans to advance; later in the day a skirmish encouraged him to cross the river. His left wing of Thracians and light troops was defeated by the Roman allies. The Macedonian phalanx in the centre at first advanced successfully against the legions, but it was soon disordered by broken ground. With greater flexibility the legionaries threw themselves into its gaps and round its flanks, where their short swords were more serviceable than the enemy's pikes (sarissas). The battle was won, perhaps without the northern wings having been engaged. The Macedonian losses were terrific. Perseus fled and finally was betrayed to the Romans, who decided to end the centuries-old monarchy and establish four republics in Macedonia.

See J. Kromayer and G. Veith, *Antike Schlachtfelder*, ii, pp. 294 ff. (1907), iv, pp. 601 ff. (1931). (H. H. Sp.)

PYGMALION, the name of two figures in classical literature and mythology.

1. In Greek mythology, Pygmalion was a king of Cyprus who fell in love with a statue of Aphrodite. Ovid, in the *Metamorphoses*, invents a more sophisticated version: Pygmalion, a sculptor, makes an ivory statue representing his ideal of womanhood, then falls in love with his own creation; Venus brings it to life in answer to his prayer.

Ovid's story was adapted by William S. Gilbert in *Pygmalion and Galatea* (1871), which appears to be the basis for the modern association of Galatea with Pygmalion's statue. George Bernard Shaw developed ironically the theme of the creative artist in

Pygmalion (1913), from which was later derived the musical play *My Fair Lady* (1956).

2. In the *Aeneid*, Pygmalion, king of Tyre, was the brother of Dido (q.v.) and the murderer of her husband. (Wm. S. A.)

PYGMY, a term used in modern anthropology as a category of size, applied to those human groups whose males are not taller than 59 in. (150 cm.) in average bodily height; a slightly taller group is called pygmoid. Races of true pygmy size have not been discovered in human prehistory. The best known are the Bambuti, who inhabit an extended area of tropical Africa. Elsewhere in Africa, some of the Bushmen of the Kalahari Desert also are of pygmy size. All Asian pygmies are known by the generic term Negrito. Each of the several groups of pygmies has its independent biological origin; however, they have in common small bodily height and certain similarities in hair and face.

Culturally, all pygmy peoples remain on the very low level of food-gatherers, neglecting agriculture and stock farming. Nearly all of them maintain close symbiotic relations with culturally advanced tribes in their environment; consequently, in most cases they have lost their indigenous language and adopted that of their hosts. See further BAMBUTI; BUSHMAN; NEGRITO; and references under "Pygmy" in the index.

See M. J. Gusinde, "Die Kleinwuchsvölker in heutiger Beurteilung," *Saeculum*, 13:211-277 (1962); C. M. Turnbull, "The Lesson of the Pygmies," *Sci. Amer.*, vol. 208 (Jan. 1963). (M. J. Gu.)

PYLE, ERNIE (ERNEST TAYLOR PYLE) (1900-1945), U.S. newspaperman, was one of the most famous war correspondents of World War II. Born near Dana, Ind., on Aug. 3, 1900, he studied journalism at Indiana University and left school a few months before his graduation to become a reporter for a small-town newspaper. Later, after various editorial jobs, he acquired a roving assignment for the Scripps-Howard newspaper chain. His daily experiences furnished him material for a column that eventually appeared in as many as 200 newspapers. His coverage of the campaigns in North Africa, Sicily, Italy, and France brought him a Pulitzer Prize in 1944, as well as several other awards. He was with the U.S. forces in the Pacific on Iwo Jima and Okinawa, during which latter campaign he visited the nearby island of Ie Shima. There, on April 18, 1945, he was killed by Japanese machine-gun fire. Compilations of his columns appeared in book form: *Ernie Pyle in England* (1941); *Here Is Your War* (1943); *Brave Men* (1944); *Last Chapter* (1946).

See Lee Graham Miller, *The Story of Ernie Pyle* (1950).

PYLE, HOWARD (1853-1911), U.S. artist and author, best known for his children's books, was born at Wilmington, Del., on March 5, 1853. He studied at the Art Students' League, New York City, and first attracted attention by his line drawings after the style of Albrecht Dürer. His magazine and book illustrations, particularly his drawings of scenes from American colonial life in New England and New Amsterdam, were of high quality. Some of Pyle's children's stories, illustrated by the author with vividness and historical accuracy, have become classics—most notably, *The Merry Adventures of Robin Hood* (1883); *Otto of the Silver Hand* (1888); and *Jack Ballister's Fortunes* (1894). Later he undertook mural paintings, executing, among others, "The Battle of Nashville" (1907) for the capitol at St. Paul, Minn.

Dissatisfied with his style in painting, he went to Italy for further study but died shortly afterward, on Nov. 9, 1911, in Florence. Pyle had established a free school of art in his home in Wilmington, where many successful American illustrators received their education.

PYLOS. The name of four ancient sites in Greece.

1. **PYLOS** (or **CORYPHASIUM**; modern **PALAEA-NAVARINO**), a town on the west coast of Messenia, noted chiefly for the part it played in the Peloponnesian War (q.v.). The Bay of Pylos (modern **BAY OF NAVARINO**), roughly semicircular, is protected by the island of Sphacteria (modern Sphagia or Sfaktiria), more than 2½ mi. long. To the north lies the lagoon of Osman Aga. North of Sphagia is the rocky headland of ancient Pylos or Coryphasium, called in modern times Palaea-Navarino, or Palaeokastro, from the Venetian ruins on its summit. The modern town of Pilos, alternatively Navarino or Neokastro, is on the southern headland

of the bay. A small island to the south of Sphagia is also called Pilos. Though the identification of Palaea-Navarino with Homeric Pylos (see 2, below) cannot be defended, it maintained some kind of settlement during the Bronze Age, for the cave on the north side of Coryphasium, traditionally associated in mythology with the herds of the Neleids and with Hermes' theft of Apollo's cattle, has been shown by excavation to have been at least intermittently occupied throughout the Bronze Age. This is reinforced by the existence nearby of two Mycenaean tholos tombs (see **AEGEAN CIVILIZATION**). The fate of the site between the end of the Bronze Age and the historical classical period is obscure; Thucydides describes Pylos as a deserted headland in 425 B.C. In May of that year, the seventh of the Peloponnesian War, the Athenians sent an expedition to Sicily under command of Eurymedon and Sophocles. With them was the general Demosthenes, who landed at Coryphasium with a body of Athenian troops and hastily fortified it. The Spartans withdrew their army from Attica, which they were then invading, and their fleet from Corcyra, and attacked Pylos vigorously by sea and land, but were repulsed; the Athenians were enabled by the arrival and victory of their fleet to blockade on the island of Sphacteria a body of 420 Spartiates together with their helots. They were overcome by a rear attack directed by a Mesenian, who led a body of men by a difficult path along the cliffs on the east, and the 292 survivors including 120 Spartiates laid down their arms 72 days after the beginning of the blockade. This made a deep impression on the whole Greek world, which had learned to regard a Spartan surrender as inconceivable. Though Pylos should have been ceded to Sparta under the Peace of Nicias (421 B.C.), it was retained by the Athenians until the Spartans recaptured it early in 409 B.C.

In the Middle Ages the name Pylos was replaced by that of Avarino or Navarino, derived from a body of Avars who settled there; the derivation from the Navarrese company, who entered Greece in 1381 and built a castle at this spot, cannot now be maintained. From 1498 to 1821 Navarino was in the hands of the Turks, except for two periods (1644-48 and 1686-1715) when it was held by the Venetians. (See **NAVARINO, BATTLE OF**.)

2. **HOMERIC PYLOS** (modern **EPANO ENGLIANOS**), an excavated site on a ridge about seven miles north of Coryphasium, three or four miles inland from the sea. Excavation begun there in 1939 and resumed in 1952 under the direction of Professor C. W. Blegen of the University of Cincinnati in collaboration with K. Kourouniotis and S. Marinatos of the Greek Archaeological Service has uncovered a Mycenaean palace and attendant buildings of great importance. Both the evidence of successive building levels within the palace and finds from a number of adjacent cemeteries show that the site was occupied from at least as early as 1700 B.C. It was violently destroyed by fire shortly before 1200 B.C. and never reoccupied. The throne room, the finest feature of the palace, with painted plaster floor and frescoed walls, is closely matched by those at Mycenae and Tiryns. This palace and its despoiled tholos tombs best suit both in dignity and position the requirements of the royal seat of Neleus and king Nestor as described by Homer, and earlier attempts to locate it at the Pylos in Triphylia, or even that in Elis (see 3 and 4, below), should be disregarded. Transcending the importance of locating Homeric Pylos was the discovery in the palace ruins of hundreds of inscribed clay tablets, baked hard by the conflagration which destroyed the site, the majority in a single "archive room." These are very closely comparable to the Linear B tablets found earlier in Crete by Sir Arthur Evans in the Palace of Knossos, and those discovered since 1952 in excavations at Mycenae. The Pylos tablets were in use at the time of the destruction, and are thus some 200 years later than the generally accepted date for the majority of the Knossian documents. The decipherment of the Linear B script by Michael Ventris and John Chadwick in 1952 (see **MINOAN LINEAR SCRIPTS**) has shown their language to be an early form of Greek. Their contents, which demonstrate the great importance of Pylos' position as an administrative and military centre, are of a purely business nature; as well as lists of persons and property, they include very detailed records of distributions and dispositions made. The implications of the presence in Crete of documents written in

Greek and the discrepancy in date between Knossos and Pylos are highly controversial.

3. PYLOS IN ELIS, on the Peneus (Pinios) River in the north-western Peloponnese.

4. PYLOS IN TRIPHYLIA (near Kakovatos). Scholarly dispute over the site of Homeric Pylos began at least as early as the 3rd century B.C. After the German excavation at the beginning of the 20th century of three Mycenaean tholos tombs (belonging to the period c. 1500 B.C.), as well as the remains of a contemporary settlement at Kakovatos, under Mt. Kaipha, Strabo's identification (vii, 348 *et seq.*) with the Pylos in Triphylia gained widespread acceptance. This lasted until the discovery of the Epano Englianos site. A too-literal interpretation of Homer's account of the journey of Telemachus from Ithaca to Pylos and from Pylos to Sparta lent additional weight to this identification.

W. C.)

PYM, JOHN (c. 1583–1643), English statesman, and a leader of the parliamentary opposition to Charles I, was the son of Alexander Pym of Brymore, Somerset, a member of a family that had held this seat in direct male descent from the time of Henry III. Pym matriculated as a commoner at Broadgates Hall (now Pembroke College), Oxford, in 1599, and entered the Middle Temple in 1602. Through the interest of Edward Russell, 3rd earl of Bedford—whose agent in the west country was Pym's stepfather, Sir Anthony Rous—Pym became receiver of the king's revenue for Hampshire, Wiltshire, and Gloucestershire.

Growth of Leadership.—As a member for Calne in the 1621 Parliament, Pym delivered a speech on Nov. 28 to “beseech the King that there may be a commission . . . to see the Laws here of England duly executed against Papists.” When James I tried to restrict the Commons' freedom of speech, Pym was a promoter of the Protestation (Dec. 18, 1621), which was entered in the Commons' journals, asserting that Parliament's privileges were “the ancient and undoubted birthright and inheritance of the subjects of England.” This protest the king tore from the journal. After Parliament's dissolution in January 1622, Pym was ordered to be confined first to his London house and afterward to Brymore, an order which remained in force for more than three months. In the 1624 Parliament Pym sat for Tavistock, which he continued to represent for the remainder of his life. There is no evidence that he took a prominent part in this Parliament or in the first Parliament (1625) of Charles I. In the 1626 Parliament Pym was one of the managers of the impeachment of George Villiers, 1st duke of Buckingham.

The outstanding event of the 1628–29 Parliament was the Petition of Right (1628), of which Pym was a leading supporter. He also spoke at length against Roger Manwaring who had preached the doctrine of nonresistance to a king, deducing that a king could levy taxes without Parliament's consent. Pym was the leader in impeaching Manwaring before the Lords, where he delivered a speech expounding the fundamental principles of government (June 1628).

Between 1629 and 1640, when no Parliament met, Pym's energies were absorbed as treasurer of the Company of Adventurers for the Plantation of the Islands of Providence and Henrietta, in the West Indies, incorporated in December 1630. After struggling for nearly 20 years, the company finally failed. Its importance

was that its members were mostly leading Puritans who had already been associated with Pym in the parliamentary struggle against Charles I and would be associated again when Parliaments were resumed. Hence when the Short Parliament met on April 13, 1640, it included a group of resolute men already accustomed to act together and to recognize Pym as leader. On April 17 Pym spoke for two hours denouncing grievances: “The First, are those Grievances which during these Eleven years interval of Parliaments, are against the Liberties and Privileges of Parliament. The Second, are Innovations in matters of Religion. The Third, Grievances against the Propriety of our goods.” “That which marked Pym from henceforth as a leader of men was the moderation combined with the firmness with which every sentence was stamped.” (S. R. Gardiner, *History of England*, vol. ix, p. 102.) Pym was concerned in an episode which led to the Parliament's abrupt end: he and others prepared a petition that the king should make terms with the Scots. To forestall this, Charles dissolved Parliament on May 5.

Pym now aimed at compelling Charles to call another Parliament. He drew up the petition (August 1640) which demanded redress of grievances, peace with the Scots, and a new Parliament, and which 12 peers presented to the king. When writs for another Parliament were issued, Pym “rode about the country to promote elections of the puritanical brethren to serve in parliament” (Anthony à Wood, *Athenae Oxoniensis*, vol. iii, p. 73)—the first election campaign in parliamentary history.

The Long Parliament.—Parliament assembled on Nov. 3, 1640. Pym was recognized at once as the leader of the opposition to the court, and his dominance grew. Believing that Thomas Wentworth, earl of Strafford, was set upon accusing the parliamentary leaders of treason for their dealings with the Scots, and that attack was the surest defense, on Nov. 11 Pym, behind closed doors, began his denunciation of him. That same afternoon Pym carried to the Lords his impeachment and a summary of the charges on which the impeachment was based. Between this date and the opening of Strafford's trial (March 22, 1641), attempts were made to win Pym and others over to the king by offering to them ministerial posts. Twice the king interviewed Pym and twice the offer of the office of chancellor of the exchequer was refused, presumably because Charles demanded the dropping of Strafford's impeachment as the price of Pym's appointment. On April 13, 1641, the last day of the impeachment trial, Pym delivered one of his most eloquent speeches, basing his attack less upon Strafford's technical breach of the law of treason than upon his betrayal of trust as the king's adviser. “Shall it be treason,” he declaimed, “to embase the King's coin, though but a piece of twelve-pence or six-pence? and must it not needs be the effect of a greater treason, to embase the spirits of his subjects, and to set up a stamp and character of servitude upon them, whereby they shall be disabled to do anything for the service of the King and Commonwealth?” Meantime some of Pym's associates were doubting whether the Lords would convict Strafford of treason on the available evidence. On April 10, therefore, they introduced a bill of attainder. Pym never agreed with this policy, believing that the impeachment should and could be carried. But it was the attainder process which was first completed and by which Strafford was executed on May 12.

Even more important than finance or Strafford to the opposition group was the subject of religion. In this matter Pym's position was different from that of most of his associates in that he was never a Puritan but was a staunch adherent of the orthodox, pre-Laudian church. In his maiden speech (Feb. 16, 1621) he had inveighed against a member named Thomas Shepherd because of his “exasperatinge one partie by that odious and factious name of Puritans.” Similarly in the 1628–29 Parliament he condemned Archbishop William Laud's Arminianism because it contravened “the 39 Articles set forth in Queen Elizabeth's time; and . . . the Articles set forth at Lambeth as the doctrine of the Church of England.” In December 1640 Pym moved Laud's impeachment, and on Feb. 24, 1641, presented the impeachment articles to the Lords. In February the Puritan members voted that a London petition against episcopacy should be sent to a com-

mittee for report, and the Anglican members voted against this; Pym voted with the Puritans, but a fellow member (Edward Bagshaw) wrote: "Mr. John Pym . . . spake to this purpose, 'That he thought it was not the intention of the House to abolish either Episcopacy or the Book of Common Prayer, but to reform both, wherein offence was given to the people.'" (E. Bagshaw, *A Just Vindication*, 1660.) When, however, Pym became convinced that the bishops were merely the king's nominees to make religious changes and to preach nonresistance, he supported the abolition of episcopacy and in May 1641 voted for the Root and Branch Bill. That this attitude was not due to a change of conviction is shown by his pamphlet *Declaration and Vindication* of March 1643 wherein he averred: "That I am, and ever was, and so will dye a faithfull son of the Protestant Religion, without having the least relation in my beliefe to those grosse errors of Anabaptisme, Brownisme, and the like."

Pym was a leading supporter of the Grand Remonstrance, which listed the grievances that had arisen in Charles's reign, and his speech on Nov. 22, 1641, helped to secure its passing, though by only 11 votes. This small majority was evidence of a reaction in the king's favour. Charles thought to take advantage of it by impeaching a member of the Lords and five members of the Commons, including Pym (Jan. 3, 1642). Next day, Charles went to the Commons to arrest the five members, only to find that "the birds are flown." This breach of privilege turned the tide decisively against Charles and made war inevitable.

The Civil War.—Pym had a large part in the preparations for war. On July 4, 1642, he was appointed one of the 15 members of the Committee of Safety, of whom five had been members of the Providence Company. After the outbreak of war in August 1642 he was the organizer who kept the parliamentary forces in the field, raising taxes and maintaining supplies. He was, in effect, the head of the executive.

At first his aim was to prevent a general war. On Nov. 9, following the Battle of Edgehill, at a conference between the two Houses, he urged a petition to the king for negotiations. The king refused to receive the petition, and Pym appealed to the City of London for its continued support. But a few days later Pym was urging that both sides should disband their armies so that negotiations should not be prejudiced by their existence. When hope of negotiations failed, Pym gave himself entirely to organizing for victory. In March 1643 he proposed an excise on the sale of all goods: though then rejected, the excise was levied four months later. In May he decided to open negotiations with the Scots. In June he reintroduced the idea—rejected the previous October—of a covenant whose signatories should pledge themselves not to lay down arms until the Reformed religion was secure. Meanwhile, negotiations with the Scots were progressing. The final terms (the Solemn League and Covenant) were that the Scots would send an army into England against the king on condition that they were paid £30,000 a month and that Parliament would establish a reformed church after the war. On Sept. 25 Parliament accepted these terms. The Scottish alliance was Pym's last notable contribution to the parliamentary cause. On Nov. 7 Parliament made him master of the ordnance; i.e., of arms stored in the Tower. On Dec. 8, 1643, he died of cancer at Derby House, Westminster, which had been granted to him as a residence. The Commons accorded him a state funeral in Westminster Abbey, where his body was buried on Dec. 13.

Family.—Pym's wife had been Anne Hooke (or Hooker), who had died in 1620. Of their nine children, four were sons. The eldest, Alexander, died unmarried. Charles became a baronet; his title and Pym's male line became extinct in Charles's son (also Charles) in 1688. Anthony emigrated, probably to St. Kitts.

Character.—Moderation of views in both religious and political questions, consistency of principles, and administrative efficiency were Pym's outstanding characteristics, and their combination explains his supremacy in Parliament. His speeches showed a sound political philosophy and logical exposition rather than rousing oratory; but they were evidently impressive and persuasive. Pym's death left a gap in the parliamentary leadership that was never again filled.

P'YŎNGYANG, capital city of the Democratic People's Republic of Korea, is located northwest along the Taedong River, 30 mi. (48 km.) from the Yellow Sea. The reputed grave of the Chinese sage Kija (1122 B.C.), legendary founder of the city, is north of the city. Artifacts found in graves testify to the high cultural level of the Chinese colony established near P'yŏngyang in 108 B.C. Walls were built to reinforce the natural protection afforded by the two rivers and hills that surround P'yŏngyang. In this well-fortified area, the Koguryo dynasty (c. 37 B.C.-A.D. 668) had its capital, until defeated by the combined forces of China and the Silla dynasty in south Korea. Thereafter P'yŏngyang continued to be a political and educational centre for northwestern Korea.

Connected with other parts of Korea by rail, motor road, and air, commercial activities in P'yŏngyang have been of paramount economic importance. Under Japanese control (1910-45) anthracite coal mines and modern industries were developed, mainly to the south of the city where rail lines converged and to the east across the Taedong River. Hydroelectric power was supplied from plants on the Yalu River and its tributaries, and from a thermal plant in the city.

In surrounding areas, heavy industries, such as the iron and steel plant at Kyŏmp'o, cement plants to the east, and chemical plants to the north, were developed. In the city an arsenal was established, and also railroad workshops, and many light industries, such as textiles, rubber shoes, cigarettes, and corn products.

During the Korean War numerous air raids devastated P'yŏngyang. It was captured by UN forces in 1950 but subsequently was lost when Chinese Communist forces entered the war. It was reported that postwar rehabilitation restored many of the industries and that many large new apartments were built.

Pop. (1944) 368,288; (1960 est.) 653,100.

PYORRHEA: see PERIODONTAL DISEASES.

PYRACANTHA, a genus of evergreen thorny shrubs of the rose family (Rosaceae), commonly known as fire thorn. There are six species native from southeastern Europe to central China. The leathery, alternate leaves are usually minutely toothed. The white flowers are in clusters, followed by red, orange or yellow berrylike fruits. *P. coccinea*, *P. crenato-serata*, and *P. crenulata* are among the best-known kinds, widely used for foundation plantings and hedges; they are prized for their ornamental foliage and showy fruit. The plants are easily grown in subtropical and temperate regions (*P. coccinea lalandii* is the most hardy form) in areas of full sun or partial shade, and are not particular as to soil type. (G. H. M. L.)

PYRAMID, in architecture, a monumental structure of stone or brick with a rectangular base and four sloping triangular sides meeting at an apex. Structures of this type were built at various times in Egypt, the Sudan, Ethiopia, western Asia, Greece, Cyprus, Italy, India, Thailand, Mexico, and on some islands of the Pacific Ocean. The most famous, and in many respects most remarkable of them all, are the pyramids of ancient Egypt, with which the present article will deal exclusively.

The ancient Egyptian term for pyramid is *mer*. The English word pyramid comes from the Greek *pyramis*, pl. *pyramides*, a word of doubtful etymology that was thought to have been derived from the ancient Egyptian *per-em-us*, a term used in a mathematical papyrus to denote the vertical height of a pyramid. A purely Greek word *pyramis* means "wheat cake," and a vague resemblance in shape may have prompted early Greeks to use it as a facetious designation of the celebrated Egyptian monuments.

The pyramids of ancient Egypt were funerary edifices. Chronologically they cover a time span of 2,700 years ranging from the beginning of the Old Kingdom to the close of the Ptolemaic Period; but the time at which pyramid building reached its acme

the pyramid age par excellence, was that commencing with the 3rd dynasty and ending with the 6th (c. 2700 to 2300 B.C.). During that 400 years the pyramid was the regular type of royal tomb. It was not, as such, an isolated structure, but was always part of an architectural complex. (See EGYPT: *Archaeology; History*.)

The essential components, during the Old Kingdom at any rate, were the pyramid itself, containing or surmounting the grave proper and standing within an enclosure on high desert ground; an adjacent mortuary temple; and a causeway leading down to a pavilion (usually called the valley temple), situated at the edge of the cultivation and probably connected with the Nile by a canal. About 80 royal pyramids have been found in Egypt, many of them, however, reduced to mere mounds of debris and long ago plundered of their treasures.

Early Forms.—The prototype of the pyramid was the mastaba, a form of tomb known in Egypt from the beginning of the dynastic era. It was characterized by a flat-topped rectangular superstructure of mud brick or stone with a shaft descending to the burial chamber far below it. Zoser (Djoser), the second king of the 3rd dynasty, employing Imhotep (q.v.) as architect, undertook for the first time the construction of a mastaba entirely of stone; it was 8 m. high and had a square ground plan with sides about 63 m. each. Once completed it was extended on the ground on all four sides, and its height was increased by building rectangular additions of diminishing size superimposed upon its top. Thus Zoser's original mastaba became a terraced structure rising in six unequal stages to a height of 60 m., its base measuring 120 m. by 108 m. This monument, which lies at Saqqarah, is known as the Step Pyramid; it is probably the earliest stone building of importance erected in Egypt. The substructure has an intricate system of underground corridors and rooms, its main feature being a central shaft 25 m. deep and 8 m. wide, at the bottom of which is the sepulchral chamber built of granite from Aswan. Zoser's Step Pyramid rises within a vast walled court 544 m. long and 277 m. wide, in which are the remnants of several other stone edifices built to supply the wants of the king in the hereafter.

A structure of peculiar shape called the Blunted, Bent, False, or Rhomboidal Pyramid, which stands at Dahshur a short distance south of Saqqarah, marks an advance in development toward the strictly pyramidal tomb. Built by Sneferu, of the 4th dynasty, it is 188 m. square at the base and approximately 98 m. high. Peculiar in that it has a double slope, it changes inclination about halfway up, the lower portion being steeper than the upper. It comes nearer than Zoser's terraced tomb to being a true pyramid. A monumental structure at Maydum, also ascribed to King Sneferu, was a true pyramid, though not originally planned as such. It is uncertain whether it was begun as a mastaba, like Zoser's tomb, or as a small step pyramid. The initial structure was gradually enlarged until it became a gigantic eight-terraced mass of masonry; then the steps were filled in with a packing of stone to form a continuous slope. The entire structure was eventually covered with a smooth facing of limestone: a geometrically true pyramid was the final result. In its ruined condition, however, it has the appearance of a three-stepped pyramid rising to a height of about 70 m. The earliest tomb known to have been designed and executed throughout as a true pyramid is the North Stone Pyramid at Dahshur, thought by some to have also been erected by Sneferu. It is about 220 m. wide at the base and 104 m. high; thus it is nearly as large as the celebrated pyramids of Giza.

Pyramids of Giza.—The three great pyramids of Giza stand on a rocky plateau of the desert a few miles southwest of Cairo. They were built by the 4th-dynasty pharaohs Khufu (Cheops), Khafre (Khefren or Chephren), and Menkure (Mycerinus), and came to be numbered among the Seven Wonders of the ancient world.

Khufu.—The largest and oldest of them is that of Khufu, now known as the Great Pyramid and called "Horizon of Khufu" by the ancient Egyptians. Perhaps the greatest single building ever erected by man, the Great Pyramid's almost perfectly square base was, when intact, 230 m. long, thus covering an area of slightly over 13 ac.; it has been calculated that St. Peter's at

TOP BY COURTESY OF EGYPTIAN STATE TOURIST ADMINISTRATION

Pyramids of Giza: (Top) Aerial view of the three pyramids; (Bottom) Section through the Great Pyramid of Khufu

Rome, the cathedrals of Florence and Milan, Westminster Abbey, and St. Paul's Cathedral could all be grouped inside that area (E. B. Smith, *Egyptian Architecture as a Cultural Expression*). The original height was 146.59 m., reduced now to 137 m. The sides rise at an angle of $51^{\circ}52'$ and are accurately oriented to the four cardinal points. The core is made of yellowish limestone blocks from the nearby Jabal al Moqattam; the outer casing (now mostly gone) and the inner passages are of finer limestone from Jabal Tura, while the burial chamber is built of huge blocks of granite from Aswan. Approximately 2,300,000 blocks of stone went into this stupendous structure, each weighing an average of $2\frac{1}{2}$ tons.

The monument is a masterpiece of technical skill and engineering ability. The geometrical precision of its layout and the accuracy of the stonecutting are truly amazing, particularly when one considers the colossal proportions of the whole and the size and weight of the blocks employed in it. The internal walls as well as the casing stones that still remain *in situ*, some of which weigh as much as 16 tons, show finer joints than any other masonry in Egypt and possibly in the world. The question of how the pyramid was built has not received a wholly satisfactory answer. The most plausible answer is that the Egyptians, who lacked tackle and pulleys for lifting heavy weights, employed a sloping embankment of brick and earth, which was increased in height and in length as the pyramid rose, and on which the stone blocks were hauled by means of sledges, rollers, and levers. According to Herodotus the road for the conveyance of building material from the river to the plateau on which the pyramid stands took 10 years to construct, while the pyramid itself took another 20 years and demanded the labour of 100,000 men. The theories that ascribe prophetic and esoteric meanings to the measurements, angles, and proportions of the Great Pyramid are wholly devoid of scientific foundation.

The entrance to the Great Pyramid is on the north side, about 18 m. above ground level. A sloping corridor descends through the

masonry, penetrates the rocky soil and ends in an unfinished underground chamber. From the descending corridor, at a point about 20 m. from the entrance, branches an ascending corridor that leads to a room known as the Queen's Chamber (although there is no evidence that it was designed for her) and to a great slanting gallery 8.50 m. high and 46.50 m. long. At the upper end of this gallery a low and narrow passage gives access to the burial room proper, usually termed the King's Chamber. Entirely lined and roofed with granite, the King's Chamber is 10.43 m. long, 5.21 m. wide and 5.82 m. high and stands at a perpendicular height of 42.28 m. from the ground. From the chamber two narrow shafts run obliquely through the masonry and reach the exterior of the pyramid; it is not known whether they served a religious purpose or were meant for ventilation. The King's Chamber contained only an empty lidless sarcophagus of red granite without ornament or inscription. Above the room are five compartments separated by horizontal granite slabs, presumably for diverting pressure from the ceiling of the burial chamber. There are scanty remains of the subsidiary buildings that once completed the architectural complex of the Great Pyramid; they show, however, that the complex comprised the usual elements. The pyramid was surrounded by a temenos wall; attached to the east side of the wall was a temple for the mortuary service of the king, and from this a long causeway descended to the valley. It is highly probable that there was, at the lower end of the causeway, a portico or valley temple, remnants of which may still lie beneath the modern village of Kafr as Samman.

Khafre and Menkure.—Next in size in the Giza group is Khafre's pyramid, which stands at a higher point of the plateau and thus appears to be taller than the larger and earlier pyramid of Khufu. It was originally 143.50 m. high, and the base 215.25 m. square. A substantial portion of its outer casing still clings around the top; it consists of slabs of Tura limestone, whereas the casing blocks that remain at the bottom of the monument are of red granite. The third Giza pyramid, erected by Menkure, formerly rose to a height of 66.50 m., less than half that of its two towering neighbours.

Other Egyptian Pyramids.—Other noteworthy pyramids belonging to the Pyramid Age are the three built at Abu Sir by kings of the 5th dynasty, of which the largest is that of Neferirkare, originally 106 m. square and 70 m. high. The other two are much smaller, but their adjoining mortuary temples appear to have been magnificent buildings decorated with excellent reliefs, some of a historical nature. The pyramids themselves were poorly constructed, and are now in a state of dilapidation.

Pyramid Texts.—The relatively small pyramids of Unas, the last monarch of the 5th dynasty, of four kings and three queens of the 6th, and of an obscure 7th-dynasty pharaoh named Ibi, all of which are at Saqqarah, are of particular interest because inscribed on the walls of their inner chambers are collections of prayers, hymns, and spells meant to ensure the welfare of the king or queen in the afterlife. These inscriptions, known as the Pyramid Texts, form the world's oldest surviving corpus of religious and funerary writings.

Middle Kingdom.—The pyramids of the Middle Kingdom exhibit some structural innovations. A small pyramid mounted on a high podium surrounded by a terraced structure with a forest of columns was the dominant feature of King Mentuhotep II's tomb-temple at western Thebes. The pyramid was solid throughout, having neither passages nor chambers, and consisted of a rubble core cased with limestone. The core of Sesostri's pyramid at Lisht consisted of a network of stone cross walls with the interspaces filled in with sand and loose blocks, the whole covered by a casing of dressed limestone blocks. This novel and labour-saving mode of construction was subsequently employed in other 12th-dynasty pyramids at Dahshur, Illahun, and Hawarah, in which, however, mud brick was used for the cross walls of the core, and as filling material as well. A further characteristic of the Middle Kingdom pyramids is the intricate design of the substructures.

No pyramid appears to have been constructed by any of the kings from the 18th dynasty to the 24th, with one exception: the

pyramid-cenotaph erected at Abydos for Queen Tetisheri by Ahmose I, founder of the 18th dynasty. Royal tombs of pyramidal form were built once again by the thoroughly Egyptianized Ethiopian rulers who held sway over Egypt as kings of the 25th dynasty in the 8th and 7th centuries B.C. They were buried in pyramids which they had erected for themselves in their homeland, at Nuri and Kurru, near the Fourth Cataract, in the northern Sudan.

Tombs of pyramidal design were built for private persons from the Middle Kingdom onward. The earliest have been found at Abydos. They were made of coarse unbaked bricks, coated with mud plaster and whitewashed. The pyramid itself was from 3 to 4 m. high and rested on a shorter rectangular podium. The coffin was deposited in a vaulted chamber which took up most of the interior of the pyramid. In the Theban necropolis, during the New Kingdom, a rather small mud-brick pyramid, sometimes topped with an apex of limestone, was a conspicuous feature of many private tombs.

PYRAMID, in geometry, a polyhedron of which one face, called the base, is any polygon and the other faces (the lateral faces) are triangles with one vertex in common. The intersections of the lateral faces are called the lateral edges of the pyramid, and their common vertex is called the vertex of the pyramid. The perpendicular distance from the vertex to the plane of the base is called the height or altitude of the pyramid. If the

REGULAR PYRAMID, OBLIQUE PYRAMID, AND FRUSTUM OF PYRAMID

base is a regular polygon, the centre of which coincides with the foot of the perpendicular from the vertex to the base, the pyramid is called regular; if the vertex is not over the centre of the base, the pyramid is said to be oblique. As in the case of prisms, pyramids are classified as triangular, quadrangular, pentagonal, and so on, according to their bases. The portion of a pyramid between the base and a plane cutting all the lateral edges is called a truncated pyramid; and if the cutting plane is parallel to the base, the truncated pyramid becomes a frustum of a pyramid. The volume of a pyramid of base area B and altitude a is $\frac{1}{3}aB$. The volume of a frustum of a pyramid with base areas B and B' and altitude a is $\frac{1}{3}a(B + B' + \sqrt{BB'})$. See SOLIDS, GEOMETRIC.

PYRAMUS AND THISBE, the hero and heroine of a Babylonian love story told by Ovid in his *Metamorphoses*. Their parents refused to consent to their union, and the lovers used to converse through a chink in the wall separating their houses. At last they resolved to flee together, and agreed to meet under a mulberry tree near the tomb of Ninus. Thisbe was the first to arrive, but, terrified by the roar of a lioness, took to flight. In her haste she dropped her veil, which the lioness tore to pieces with jaws stained with the blood of an ox. Pyramus, believing that she had been devoured by the lioness, stabbed himself. Thisbe returned to the rendezvous, and finding her lover mortally wounded, put an end to her own life. From that time, legend holds, the fruit of the mulberry, previously white, was always black.

PYRRARGYRITE, a mineral consisting of silver sulfantimonite, known also as dark red silver ore, is an important source of the metal. It is closely allied to, and isomorphous with, the corresponding sulfarsenite known as proustite (*q.v.*), or light red

silver ore. "Ruby silver" or red silver ore (German *Rotgültigerz*) was mentioned by Georgius Agricola in 1546, but the two species were completely distinguished by Joseph Louis Proust in 1804.

The composition of pyrargyrite is Ag_3SbS_3 . The colour is usually grayish black and the lustre metallic-adamantine; large crystals are opaque, but small ones and thin splinters are deep ruby red by transmitted light; hence the name, from the Greek words for "fire" and "silver." The streak is purplish red, thus differing markedly from the scarlet streak of proustite and affording a ready means of distinguishing the two minerals. The mineral occurs in metalliferous veins with calcite, argentiferous galena, native silver, native arsenic, etc.

The best crystallized specimens are from St. Andreasberg in the Harz Mountains and Freiberg in Saxony, and Guanajuato, Mex. It is found at Cobalt, Ont., and is not uncommon in silver mines in the United States in Colorado, Nevada, New Mexico and Idaho, but rarely as distinct crystals; and it has been found in Cornish mines.

PYRAZINES (PIAZINES or PARADIAZINES), in organic chemistry, nitrogenous compounds containing a ring composed of four carbon atoms and two nitrogen atoms, the latter being in the 1:4 relationship.

Pyrazine, $\text{C}_4\text{H}_4\text{N}_2$, crystallizes from water in colourless prisms having a heliotrope odour; it melts at 55°C and boils at 115°C . Its structure, which is analogous to that of benzene (*q.v.*), may

I

II

III

be described as a resonance hybrid between I and II (*see* RESONANCE, THEORY OF). As with benzene, the structure is commonly expressed by the conventional symbol III.

Important derivatives of pyrazine include: hexahydropyrazine, or piperazine; the diketopiperazines or amino-acid anhydrides, which are obtained by the elimination of alcohol from the esters of α -amino acids; and the various groups of azine dyes.

(G. W. Wd.)

PYRAZOLES are a class of organic compounds containing a doubly unsaturated five-membered ring with three carbon atoms united to two adjacent nitrogen atoms. Some of the pyrazoles have medical and industrial uses. The structure of the parent compound itself, pyrazole, and the numbering system commonly used for derivatives, is shown in formula I. The electron configuration of the pyrazole ring system is related to that of benzene and is responsible for the considerable stability of compounds with this structure. Dihydro- (II) and tetrahydro-pyrazoles (III) are called pyrazolines and pyrazolidines, respectively. While most compounds related to structures I, II, and III are of interest only to the organic chemist, some pyrazole derivatives with an oxygen atom at position 5 (pyrazolin-5-ones) have considerable value as drugs to combat pain and fever, and as dyes.

The discovery of the analgesic and antipyretic properties of antipyrine (2,3-dimethyl-1-phenyl-3-pyrazolin-5-one) (IV) in 1883 by Ludwig Knorr of Germany was the beginning of a systematic search for other pyrazole derivatives with more satisfactory properties. Aminopyrine, the 4-dimethylamino derivative of antipyrine, was the result of these efforts; it has largely replaced antipyrine because of its higher effectiveness and more protracted action. Many 3-pyrazolin-5-ones have been synthesized and tested for activity as antipyretics and analgesics, but only a few have been able to compete with aminopyrine to any extent. Antipyrine, aminopyrine, and related compounds may adversely affect the mucous membranes, skin, and blood; for this reason they are little used in the United States, although world consumption in the 1960s was around 300,000 pounds a year and pyrazolinone analgesics were the drugs of popular choice in Europe, South America, and the Middle East. Phenylbutazone (1,2-diphenyl-4-

I

II

III

IV

butyl-3,5-pyrazolidinedione), a pyrazole derivative with two oxygen atoms, has been found to be useful in the treatment of certain forms of arthritis.

The most important commercial use for pyrazole derivatives is as textile and foodstuff dyes. Most of these dyes are pyrazolin-5-one derivatives containing an arylazo group (two nitrogen atoms attached to an aromatic ring) at position 4. The outstanding features of the pyrazolinone dyes is their excellent fastness to light and severe wet treatments. Complex formation with metal salts is frequently used to upgrade the fastness of the dyes and to obtain more desirable colour shades.

Colour photography makes extensive use of pyrazolinone derivatives as colour couplers, sensitizers, and developing agents.

See T. L. Jacobs, "Pyrazoles and Related Compounds," in *Heterocyclic Compounds*, ed. by R. C. Elderfield (1957); R. H. Wiley and P. F. Wiley, *Pyrazolones, Pyrazolidones and Derivatives* (1964). (G. L. C.)

PYRENEES, a range of mountains between the Bay of Biscay and the Mediterranean, separating the Iberian Peninsula from France. In general the crest line marks the frontier between France and Spain, though important exceptions are the Valle de Arán, which is Spanish though on the north slope of the Pyrenees, and the whole of the Maladeta Massif, which is in Spain. Another exception is the French area of the Cerdagne, to the south of the main watershed.

The range is about 250 mi. (400 km.) long, has an approximate maximum width of 60 mi. (100 km.), and a steeper northern slope. It can be divided into three geographical regions: the western, central, and eastern Pyrenees. The western Pyrenees, which extend westward from the Col de Somport (Spanish Puerto de Somport), have a generally rounded, subdued relief; their crest line, seldom exceeding 6,500 ft. (2,000 m.), declines gradually to the west. Eastward the high mountains of the central Pyrenees maintain a level exceeding 6,000 ft. (1,800 m.) for over 100 mi. and have areas of permanent snow. The highest peaks are the Pico de Aneto (11,168 ft. [3,404 m.]), highest summit of the Maladeta Massif, the Pico de Posets (11,046 ft. [3,367 m.]), and Mont Perdu (Spanish Monte Perdido; 11,007 ft. [3,355 m.]). The eastern Pyrenees, with their Mediterranean influences, extend eastward from the Col de la Perche. Their decline in height is more sudden than that of the western Pyrenees and longitudinal valleys assume a greater importance in their relief.

In spite of Louis XIV's statement that "the Pyrenees exist no longer," the central mountains are still a barrier to communications, with main road passes closed for more than half the year. The north-south valley routes often end in formidable cirques or cross the frontier ridge as mule tracks. Apart from the important easier routes round the coastal flanks of the range there are eight principal main road passes: Roncesvalles (Ibañeta; 3,468 ft.); Somport (5,354 ft.); Pourtalet (Portalet; 5,880 ft.); the road southward from Viella in the Valle de Arán which tunnels for $3\frac{1}{2}$ mi. beneath the Puerto de Viella; Puerto de la Bonaigua (6,798 ft.); Port d'Envalira (8,022 ft.), the highest pass of the Pyrenees, in Andorra; Col de Puymorens (6,283 ft.); and Col de

TOPOGRAPHY OF THE PYRENEES MOUNTAINS

la Perche (5,174 ft.). Communication laterally between adjacent north-south valleys remains difficult, though in France the tourist Route des Pyrénées, with such spectacular passes as the Col du Tourmalet (6,939 ft.), south of the Pic du Midi de Bigorre (9,440 ft.), provides a link between valleys in the east. On the Spanish side individual valleys remain single units, with their own local wines and other produce.

Geology.—The geological history of the Pyrenees is epitomized in De Sitter's statement: "In contrast with the Alps, the Pyrenees are more of a rejuvenated Hercynian mountain chain than a Tertiary structure." Between the Aquitaine and Ebro basins to the north and south, the Pyrenean structural belt can be divided into five components: (1) A northern marginal trough with relatively gently folded Upper Cretaceous and Eocene rocks such as the limestones of the Petites Pyrénées; (2) the Ariège zone of folded Mesozoic rocks surrounding minor massifs of Paleozoics, with which they are infolded. A southern boundary for the zone is provided by the important North Pyrenean fault complex; (3) the axial zone with its cleaved and folded Paleozoics and associated igneous rocks, such as the intrusive granites of the Maladeta Massif and the andesite intrusion of the Pic du Midi d'Ossau; (4) the zone of Mont Perdu, a narrow belt of folded Mesozoic rocks, corresponding to zone (2) but of different tectonic form. Here are structures due to gravitational gliding such as the "cascade" of folds in the Upper Cretaceous and Eocene limestones of Mont Perdu and the Val d'Ordesa (a Spanish national park); and (5) a southern marginal trough with thick folded, mainly Eocene, sediments.

Folding in the Pyrenees may be ascribed to three main phases. Precambrian rocks are poorly known but the Lower Paleozoic rocks, such as the graptolitic shales of the Silurian, were cleaved and folded by the first, Hercynian, phase of Upper Devonian and Carboniferous times. Later Devonian and Carboniferous rocks show much lateral variation in response to the active elevations of the time. The Paleozoic rocks of the axial belt are cut by granite and other intrusions following upon the Hercynian movements. The North Pyrenean fault system was initiated during the orogeny; to the north of it folds and faults elevated the minor massifs of the Ariège zone, later to be surrounded by Mesozoic sediments.

Subsequently the axial zone (except for the deposition of continental Triassic rocks) remained essentially geanticlinal. Two phases of Alpine earth movements occurred in late Cretaceous and post-Eocene times. The former accentuated the elevation of the axial zone. In the marginal troughs the marine rocks of the Jurassic and Lower Cretaceous were folded. The post-Eocene movements again affected the marginal troughs and produced the gravitational gliding structures to the south of the axial zone.

Later geological events have been intermittent elevation of the

range and the spread of extensive post-Eocene conglomerates and sandstones northward and southward from the mountain belt. This detritus may obscure the earlier fold structures as in the case of the Tertiary fan of Lannemezan, which spreads across the northern marginal trough.

Glaciation.—The present-day permanent glaciers of the central Pyrenees occupy only a few square miles. Individually they are very small, occurring especially on the north-facing summit slopes, the largest group being in the Maladeta Massif. There, to the north of the Pico de Aneto, is the largest individual glacier which is about $\frac{1}{2}$ mi. long and just over a mile wide. It is not, however, a valley glacier but merely a sheet with an irregular lower edge.

Impressive cirques, such as that of Gavarnie (*q.v.*) and the Cirque de Troumouse, and pyramidal peaks, such as the Pic du Midi d'Ossau, testify to the greater extent of the Pleistocene glaciation. The north-south valleys have moraines and hanging tributaries and, in France, there is evidence that the ice along them reached as low as just over 1,000 ft. above present sea level.

Drainage.—Viewed from the Boulevard des Pyrénées at Pau the north front of the range appears as a mountain wall, into which penetrate the deep glaciated north-south valleys initiated by consequent streams upon the original axial uplift. These are characterized by "flats" floored by glacial drift, separated by gorges or rapids where there are morainic barriers. Generally, on the French side, there is little longitudinal adaptation to the various rock types. The main rivers, beginning in the west, include the Gave d'Aspe and the Gave d'Ossau, which converge to form the Gave d'Oloron. The Gave de Pau, which rises in the Cirque de Gavarnie, flows northward to Lourdes before turning northwestward through Pau. These *gaves* (a local term for a mountain torrent) are tributaries of the Adour, which forms the next important Pyrenean river. It rises to the east of the Pic du Midi de Bigorre, whence it flows in a generally northerly direction before turning west. The central and much of the eastern Pyrenees are drained by the Garonne, with its tributary the Ariège. The Garonne rises in the Valle de Arán where an east-west longitudinal valley follows the strike of the Paleozoic sediments and in part runs between two igne-

THE GARONNE RIVER AT SAINT-BÉAT IN THE HAUTE-GARONNE REGION OF THE PYRENEES

ous masses. One headstream rises at the eastern end of the valley, the other from a cavern to the west. In the eastern Pyrenees the rivers Agly, Têt, and Tech occupy west-east longitudinal valleys in their courses to the plain of Roussillon. There subsidences associated with the Mediterranean border contribute to the different relief pattern.

On the Spanish side of the Pyrenees is a complex area of sierras and deep valleys drained by the northern tributaries of the Ebro. These, too, cut across the structural grain, but longitudinal elements are stronger. The Aragón, for example, west of Jaca, has an important longitudinal portion of its course. The longitudinal elements of the drainage are separated by strike ridges cut in the extensive Tertiary sediments of the southern marginal trough.

Underground drainage related to the various Paleozoic to Tertiary limestones is significant in the Pyrenees and the French speleologist Norbert Casteret explored many of the underground watercourses and caverns. One of his most important discoveries came after four years' (1928-31) investigation of the supposed connection between the Trou du Toro (6,561 ft.) in the Maladeta Massif, where meltwaters from the local glaciers and snowfields make an impressive disappearance below ground, and the Goueil de Jouéou (4,610 ft.) whence, in the Valle de Arán, the western headwaters of the Garonne appear. Proof of the connection came finally in 1931 when fluorescein thrown into the Trou du Toro coloured the emerging waters of the Garonne.

Economy.—The traditional occupation of pastoral farming, with its associated fodder crop production, still dominates the scene in the Pyrenean valleys. Cattle (for milk, cheese, and meat) and sheep (for wool, meat, and cheese) are both involved in transhumance between the valleys and the high summer pastures. Market gardening takes place in the lower valleys in France.

The woodlands have gradually been felled for timber, for charcoal for local iron forges, and to make clearances for pasture. Garigue and maquis have replaced the trees, but forestry remains important and reforestation continues. The forest types vary: in the western Pyrenees affected by humid Atlantic winds, ash and chestnut are characteristic; in the central area beech is succeeded at higher levels by conifers; and in the drier east Mediterranean oaks are succeeded by pines. Tree cover is thinner in Spain than France because of the generally drier climate.

The mineral wealth of the Pyrenees is not great, though there are iron deposits and natural gas in France, limestone and talc are quarried, and some coal occurs in Spain. Local industries are expected to thrive when the great potential of hydroelectric power is developed. This potential lies in the deep, steep-sided valleys, the many high-level, rock-basin lakes, and the heavy precipitation. Though installations were small, in the early 1960s the Pyrenees provided about one-sixth of France's hydroelectric power and new developments were occurring also in Spain.

BIBLIOGRAPHY.—H. Belloc, *The Pyrenees*, 4th ed. (1928); L. U. de Sitter, *Structural Geology* (1956); N. Casteret, *Ten Years Under the Earth* (1939). (C. H. Ho.)

PYRÉNÉES-ORIENTALES, a frontier *département* of southern France, formed in 1790 from the province of Roussillon (q.v.) and the region of Cerdagne (Cerdaña), which had become part of France in 1659, together with small adjacent areas of Languedoc. It is bounded south by Spain, west by the Pyrenean state of Andorra, northwest by the *département* of Ariège, and north by that of Aude, and to the east fronts the Mediterranean Sea from the Étang (Lagoon) de Leucate to the Spanish frontier at Cap Cerbère. Area 1,600 sq.mi. (4,144 sq.km.). Pop. (1962) 251,231. The eastern Pyrenees (Carlite, 9,583 ft. [2,921 m.]) largely represent the crystalline core of the mountain system and extend right to the Mediterranean as the Albères range. Between the Albères and the crystalline Corbières Massif to the north lies the plain of Roussillon, a downfaulted basin, formerly occupied by a gulf of the sea that has been filled with detritus by the Tech, Têt, and Agly rivers. The western part of the *département* consists of the high mountain valleys of these rivers, between west-east mountain spurs. Cultivation of cereals, potatoes, and fodder

crops is carried on up to about 5,000 ft. (1,500 m.), and a pastoral economy uses summer grazings that are snow-covered for several months. Below the tree line at about 7,000 ft. the forests of the eastern Pyrenees have been ravaged during the centuries by the needs of shipbuilding and iron industries and especially by the uncontrolled grazing of sheep and goats. At higher altitudes are the remains of conifer forests, with hardwoods, especially oaks, below. Altitudinal zoning of vegetation is exceptionally well developed on Canigou (9,137 ft. [2,785 m.]), which dominates the plain of Roussillon. At lower altitudes the mountains are covered with Mediterranean scrub, and the Albères has some cork oak and chestnut woodland.

The plain of Roussillon experiences the characteristically mild winters and dry summers of the Mediterranean climate, the average monthly temperatures at Perpignan ranging from 6° to 22° C (44°-73° F), with an annual rainfall of only 22 in. (560 mm.). The normal mildness encourages the cultivation of delicate and out-of-season crops, but protection needs to be provided against the *tramontane*, a strong, cold wind from the northwest, to which Roussillon is subject. There is a sharp distinction in the cultivated area between (1) the irrigated tracts (*regadiu*), chiefly along the Tech and Têt, watered by channels (*rechs*) from these rivers and devoted to intensive production of peaches and apricots or to a continuous succession of vegetable crops behind the shelter of cypress windbreaks; and (2) the unirrigated cultivation (*aspre*) of gravel terraces and lower hill slopes. There the traditional Mediterranean dry farming, based upon wheat, olive, and vine, has largely been replaced by vineyards. Rivesaltes and Banyuls are well-known wines, the latter being produced from terraced vineyards on the Albères behind its rocky coast. Perpignan has a large distilling industry, and *Byrrh* (a well-known apéritif) is made at Thuir nearby.

The high-grade iron ore of Canigou has long been worked and still supports a local iron industry at Prades and at the modern electric furnaces of Villefranche-de-Conflent. Hydroelectric power has been developed chiefly by stations on the Têt River. Among several notable spa resorts, the chief are Amélie-les-Bains and Vernet. The tourist industry has been greatly stimulated by the construction of motor roads. That from Toulouse over the Col de Puymorens (6,283 ft. [1,915 m.]), skirting Andorra, is joined by a road from Perpignan at the head of the Têt Valley (Conflent) at the frontier post of Bourg-Madame. The lower, historic route farther east by the Col du Perthus (942 ft. [287 m.]), which was used by Hannibal, is open throughout the year. The railway tunnels the ridges of the Albères near the coast, where little coves provide small and picturesque sardine and anchovy fishing ports at Collioure and Port-Vendres.

Perpignan, the historic capital of Roussillon, with the ancient palace of the kings of Majorca embedded within the massive citadel built by Sébastien le Prestre de Vauban, is the largest town and *préfecture* of the *département*. Since 1602 it has replaced Elne as the centre of a bishopric. The *département* comes under Montpellier for the administration both of justice and of education. It is divided into three *arrondissements*, centred upon Perpignan, Prades, and Céret. (AR. E. S.)

PYRETHRUM, the name for certain species of the genus *Chrysanthemum* in which the aromatic flower heads, powdered, constitute the active ingredient in the insecticide commonly called pyrethrum. These plants were formerly considered a separate genus, *Pyrethrum*. The typical species, the perennial *C. coccineum*, is the florists' pyrethrum, commonly called painted lady. Large daisylike flowers—deep rose-coloured petals surrounding the yellow centre or disk—are borne on long simple stems above the crown of finely cut leaves. Modern varieties are remarkable for the colours of their flowers—white, lilac, and shades of red. They are used in flower borders and as cut flowers.

The powdered flower heads of *C. coccineum*, *C. cinerariaefolium*, and *C. marschallii* are chief sources of the insecticide. The active substances in pyrethrum—pyrethrins I and II and cinerins I and II—are contact poisons for insects and cold-blooded vertebrates. The concentrations of pyrethrum powder used in insecticides are nontoxic to plants and higher animals; therefore,

these insecticides find wide use in household and livestock sprays as well as in dusts for edible plants.

These highly aromatic plants, native to southwestern Asia, are now widely cultivated as fine hardy perennial garden subjects; they are grown for pyrethrum powder chiefly in Africa, Japan, and India. Seeds sown in the spring in ordinary well-drained garden soil in full sun will produce plants that bloom the following year; plants may be increased by division of the crown after flowering.

Pyrethrum root, or Spanish pellitory, is the root of *Anacyclus pyrethrum*, of North Africa; it was formerly used for relief of dental pain and facial neuralgia. (N. Tr.; X.)

PYRGOS (modern Greek Πύργος), a town of Greece and capital of the *nomos* (prefecture) of Elis (Ilia), is situated in the *demos* of Letrinoi, 43 mi. (69 km.) SSW of Patras (Patrai) and about 4 mi. N of the Alpheus (Alfios) River. Pop. (1961) 20,558. It stands on an outcrop of marl overlooking the coastal plain between the Peneus (Pinios) and Alpheus, and occupies the site of the ancient Letrini, one of the townships of Elis. It first became important during the Frankish occupation of the Peloponnese in the 13th century A.D. It is connected with its port Katakolon, 7½ mi. W; with Patras, Olympia, and Kalamata (Kalamai) by rail; and is a centre from which the local currant crop is exported. Pyrgos has frequently been damaged by earthquakes.

(W. G. F.)

PYRIDINE, a colourless, liquid, nitrogenous base with a pungent odour, belongs to the class of heterocyclic aromatic bases and is the most fully investigated member of that class. It is obtained primarily from the noncondensable coke-oven gases together with the homologous methylpyridines, the picolines. Structurally, pyridine (C_5H_5N) may be regarded as benzene in which one CH group is replaced by N, and in analogy with benzene there is an entire series of compounds derived from pyridine as the parent compound. Although the pyridine nucleus does not occur so frequently in natural products as the derived condensed systems quinoline (*q.v.*) and isoquinoline, it is found in the alkaloids of the pomegranate, lobelia, hemlock, areca and tobacco species and in the B-complex vitamins, nicotinic acid and pyridoxine, compounds of great physiological and commercial significance. Pyridine, the picolines and the higher homologues such as the lutidines (dimethylpyridines) and collidines (trimethylpyridines), which are found in the light-oil and middle-oil fractions from coal tar, are known as the pyridine bases. These bases were first isolated and characterized by T. Anderson in England (1846-57) in his investigation of the oil formed in the dry distillation of bones; α -picoline, the first of these bases to be isolated as a pure substance, had been obtained from the basic constituents of coal tar in 1846. Pyridine and several of its homologues were obtained from bone oil shortly thereafter. Since their formation occurs on dry distillation only if the bones still contain unsaponified fat, they are regarded as end products of the interaction of acrolein formed from the glycerol of the fat and the ammonia from the nitrogenous constituents.

In addition to limited supplies from bone oil, pyridine bases have been commercially available from the condensation products of the coking of coal since 1860. With the advent of the successful use of the by-product oven in Germany in 1881 and its introduction later into the U.S. and England, the coal-tar industry was firmly established, but it was not until spurred by the demands of the growing pharmaceutical industries that, around 1920, the production of pyridine bases from coal tar began to expand rapidly. The pyridine and pyridine bases produced in the coking process are recovered from the ammonia saturator liquor from the ammonium sulfate crystallization process at the by-product coal-carbonization plant and from a low-boiling fraction (middle oil) of the coal tar at the refining plant. The mother liquors from the distillation of the middle oil, after removal of naphthalene by centrifugation, are extracted with caustic soda, the residual oil distilled, the distillate treated with sulfuric acid, the acid solution neutralized with ammonia, the crude wet pyridine bases dried by azeotropic distillation with benzene and refined by fractional distillation to give some pyridine and picolines, but mainly the higher

alkylated pyridine and quinoline bases. The ammonia saturator liquors, containing about 60% of the 0.15 lb. of total pyridine and quinoline bases per ton of coal coked, are saturated with ammonia in a continuous neutralizing still and distilled to give crude pyridine bases containing 15%-20% water, dried by azeotropic distillation with benzene and fractionated to yield pyridine, α -picoline, a β -picoline fraction and a mixture of higher alkylated pyridines.

Synthetic Processes.—The inherent limited production of pyridine bases from the coking industry encouraged commercial development of synthetic processes to meet the increasing demands

Pyridine syntheses

for intermediates for the manufacture of pharmaceuticals, copolymers and detergents.

Examples of such processes are given:

1. Since pyrolysis of bones, shale and coal is actually a synthesis of pyridine bases, various pyrolytic syntheses by the vapour-phase reaction of ammonia with acrolein, acetylene derivatives, acetaldehyde or ethyl alcohol and hydrogen by passage of the mixed gases over metal oxide catalysts at 350°-500° C. have been investigated.

2. The reaction of paraldehyde with aqueous ammonia at 200°-250° C., the so-called Chichibabin synthesis, gives 70%-80% yields of 2-methyl-5-ethylpyridine (MEP, aldehyde collidine) with 5%-10% of α -picoline as by-product. MEP is oxidized to the corresponding dicarboxylic acid, which loses carbon dioxide at high temperatures and gives 75% yields of nicotinic acid. Catalytic dehydrogenation of MEP in the presence of an inhibitor gives 2-methyl-5-vinylpyridine (MVP), a valuable monomer for the preparation of synthetic rubbers and acrylonitrile polymers.

3. The classical Hantzsch pyridine synthesis (1882) involves the condensation of two moles of acetoacetic ester with one mole of aldehyde and ammonia (β -aminocrotonic esters can substitute for a mole of acetoacetic ester and ammonia). The dihydropyridine derivatives formed are readily oxidized to a substituted pyridine derivative, or the ester may be hydrolyzed and decarboxylated to bases such as 2,6-lutidine or collidine. Many modifications of this classical synthesis have been developed; the Knoevenagel-

Fries condensation substitutes a mole of malonic ester for a mole of acetoacetic ester; the Guareschi-Thorpe modification involves the use of cyanoacetic acid derivatives; and the Gattermann-Skita method employs compounds of the type of dichloromethylamine reacting with diethyl sodiomalonate.

4. The pyridine ring can also be formed by condensation of hydroxylamine with 1,5-diketones, by replacement of the ring oxygen atom of pyrones with an N atom and by expansion of the five-membered ring of pyrroles.

Properties.—Pyridine is a stable, flammable, colourless liquid volatile with steam, m.p. -42°C .; b.p. 115.3°C . It readily adsorbs moisture to form an azeotrope corresponding to $\text{C}_5\text{H}_5\text{N} \cdot 2\text{H}_2\text{O}$, b.p. $92^{\circ}-3^{\circ}\text{C}$. It is an excellent solvent for most organic compounds and gives conducting solutions with silver, copper, lead, mercury and iron halides, nitrates and acetates. It is a completely water-soluble, weak base (K_b , 2.3×10^{-9}) forming salts with strong acids and as a tertiary amine yields typical quaternary salts.

The higher alkylpyridinium halides such as N-cetylpyridinium chloride are valuable cationic germicides. Pyridine, toxic to humans in daily doses of 1.8–2.5 c.c. per day, is detoxified in the dog by conversion to N-methylpyridinium hydroxide. Like ammonia it combines with the metals of the transitional groups of the periodic table to give stable co-ordination compounds whose study has been important in the development of the theory of co-ordination and in the stereochemistry of the metals. Oxidation of quinoline to quinolinic acid, in which the benzene ring is destroyed while the pyridine ring remains intact, shows the extreme stability of the ring to oxidation. Consequently, pyridine can be used as a solvent for oxidations and the pyridine homologues are oxidized to the corresponding pyridinecarboxylic acids. Degradation of alkaloids containing pyridine, quinoline and isoquinoline rings by vigorous oxidation often provides valuable structural information.

The similarity of behaviour of pyridine to that of benzene led to the adoption of a formula for pyridine similar to the Kekulé formula for benzene, but, at present, pyridine is considered to be a resonance hybrid of a number of structures which differ in their electronic distribution.

Pyridine is readily reduced catalytically, electrolytically or by sodium in alcohol to the saturated hexahydro derivative piperidine, $\text{C}_5\text{H}_{11}\text{N}$, m.p. -9° to 17°C ., b.p. 106°C ., d_4^{20} 0.8622, K_b 1.6×10^{-3} . It is a colourless liquid with a characteristic ammoniacal odour miscible with water and most solvents. It forms salts, ring-substituted derivatives and well-known N-derivatives such as N-acetyl- and N-benzoylpiperidines. Piperidine can be obtained by the hydrolysis of the alkaloid piperine, occurring in various peppers, and is present in coniine, the poisonous principle of hemlock, as the ester 2-propylpiperidine. In addition to the various synthetic anesthetics such as eucaine, prepared from 4-piperidone, the analgesic mepiperidine hydrochloride is an important derivative of piperidine. The elucidation of the structure of the pyridine carboxylic acids was an important stage in determining the structure of many alkaloids. The more commercially important carboxylic acids are the vitamin nicotinic acid, and isonicotinic acid, whose hydrazide has found use as an antitubercular agent. A synthesis of isonicotinic acid from citrazinic acid, produced by the amidation of citric acid, has been commercially developed.

Other important pyridine derivatives of pharmaceutical interest in addition to pyridoxine and sulfapyridine are the urogenital analgesic 2,6-diamino-3-phenylazopyridine hydrochloride, the X-ray contrast materials sodium iodomethamate and iodo-pyrazet and the antihistaminic 2-benzyl (2-dimethylaminoethyl) amino pyridine hydrochloride. In addition to the above-mentioned MEP and MVP, 2-vinylpyridine, used as a monomer for copolymerization with butadiene, styrene and acetonitrile, and the water-repellent stearamidomethylpyridium chlorides, produced by heating stearamide, paraformaldehyde and pyridine hydrochloride in pyridine, are important commercial pyridine base derivatives.

(C. R. AL.)

PYRIMIDINES: see NUCLEIC ACIDS.

PYRITE or IRON PYRITES, also known as fool's gold, is a naturally occurring iron disulfide. This compound is dimorphous, existing both as orthorhombic marcasite (white iron pyrites) and as cubic pyrite (see also MARCASITE). The name pyrite comes from the Greek *pyr*, "fire," in allusion to the fact that it emits sparks when struck by steel.

Nodules of pyrite have been found in prehistoric burial mounds, suggesting their use as a primitive means of producing fire. Wheel-lock guns, in which a spring-driven serrated wheel rotated against a piece of pyrite, were used for a period before the development of the flintlock.

Pure pyrite contains 46.67% iron and 53.33% sulfur. Nickel and cobalt may replace some of the iron, but the frequent presence of gold and copper is probably because of microscopic inclusions of other minerals containing these metals. In some localities auriferous pyrite is an important source of gold, and a considerable quantity of copper is obtained from certain pyrite deposits. In addition to the gold and copper which it may contain, the chief commercial use of pyrite is as a source of sulfur and sulfur dioxide (SO_2), used for bleaching and in the manufacture of sulfuric acid (*q.v.*).

Unlike most sulfide ores, which have to be roasted to obtain the SO_2 , pyrite contains such a high percentage of sulfur that when reasonably pure, and in finely divided form, it will sustain its own combustion without the aid of an external source of heat. For the manufacture of sulfuric acid it is desirable that the ore be as free as possible from arsenic. Because of the availability of much better sources of iron (hematite, goethite and magnetite), pyrite is not generally used as an iron ore, although small quantities of sinter, or cinder from the burning of pyrite, may be mixed with the higher-grade ores.

For many years Spain was the largest producer, the large deposits at Riotinto being important also for copper. Other important producers are Japan, the United States (Tennessee, Virginia, California), Canada, Italy, Norway, Portugal and Czechoslovakia. Beautiful crystals are found in many localities, including Cornwall in England; Westphalia in Germany; St. Gotthard in Switzerland; Elba and Piedmont in Italy; and Colorado, New Jersey, Pennsylvania, Arizona and Utah in the United States. (See also NATURAL RESOURCES: *Nonmetallic Minerals*.)

Pyrite crystals are common and sometimes are beautifully developed. The commonest forms are the cube, octahedron and pentagonal dodecahedron (pyritohedron), either separately or in various combinations. The cubes frequently have very characteristic striations parallel to the cube edges. Penetration twins also occur. The hardness of pyrite is 6 to 6.5 and the specific gravity about 5, varying somewhat with composition. A conchoidal fracture is usually conspicuous on crystals and on coarse-grained material. It sometimes has an iridescent tarnish. The lustre is bright metallic and the streak greenish-black. The colour is brass yellow. In comparison marcasite is a paler yellow, while chalcopyrite (copper pyrites) is much deeper yellow as well as softer.

Pyrite weathers rapidly to hydrated iron oxide, goethite or limonite; pseudomorphs of goethite after pyrite are common. They vary from a thin coating of goethite on the pyrite crystals to those which have been completely altered. This weathering produces a characteristic yellow-brown stain or coating, such as is observed on rusty quartz or in the residual iron deposits, or "gossan" capping on exposed sulfide ore bodies.

Pyrite is a mineral of very wide distribution and it occurs under extremely varied conditions of mineral formation; thus it is said to be a "persistent" mineral. It has been reported as resulting from magmatic segregation; it occurs as an accessory mineral in igneous rocks and has been found as a sublimation product at Vesuvius. Especially important are the hydrothermal deposits, from medium- to high-temperature solutions. Pyrite is very common in vein deposits with other sulfide minerals and with quartz. It is common in sedimentary rocks, such as shale, coal and limestone. Pyritized fossils are of frequent occurrence in these rocks.

Pyrite is found in large deposits in contact metamorphic rocks. Deposits of copper-bearing pyrite are widely distributed and often of great size. They usually occur in or near the contact of erup-

tive rocks with schists or slates, the presence of the igneous rocks probably being connected genetically with the origin of the ore. Well-developed cubes of pyrite occur with magnetite in a chlorite schist at Chester, Conn.

Pyrite Group.—Pyrite has the composition FeS_2 and is the most important member of the pyrite group, an isomorphous series which also includes bravoite (Ni,FeS_2); laurite, RuS_2 ; sperrylite, PtAs_2 ; hauerite, MnS_2 ; and penroseite, $(\text{Ni,Cu,Pb,Co})\text{Se}_2$. It is also closely related structurally to the cobaltite group, which consists of cobalt and nickel minerals in which the sulfur pairs (S_2) of pyrite are replaced by arsenic-sulfur (AsS) and antimony-sulfur (SbS), resulting in lower symmetry. (L. S. RL.)

PYROGALLOL (PYROGALLIC ACID), a trihydroxybenzene, $1,2,3\text{-C}_6\text{H}_3(\text{OH})_3$, is used as a developer in photography, as an antioxidant in lubricating oils, and as an oxygen absorbent in gas analysis. It has antiseptic properties and is employed medicinally in the treatment of psoriasis. It was first prepared by C. W. Scheele in 1786 by heating gallic acid. The process of manufacture is still based on Scheele's procedure. Pyrogallol crystallizes in colourless leaflets or needles, melts at 134°C , and is easily sublimed; it distills at 309°C under ordinary pressure with partial decomposition. It dissolves in $2\frac{1}{2}$ parts of water at 13°C , and its aqueous solution develops a blue colour with ferrous sulfate containing a little ferric salt. Its alkaline solution, when exposed to air, rapidly becomes black because of the absorption of oxygen with the production of complex coloured substances. (G. T. M.)

PYROLUSITE, a mineral composed of manganese dioxide of great importance as an ore of manganese. It is used in the manufacture of steel and manganese bronze, as an oxidizing agent in the manufacture of chlorine and in dry cells, in glass, ceramics, and paint pigments. It is mined in the U.S.S.R., Germany, Brazil, India, the United States (West Virginia, Georgia, Tennessee, the Lake Superior district, and California), Cuba, Morocco, Ghana, and South Africa. This compound, which has the formula MnO_2 , is dimorphous, occurring both as an orthorhombic form, ramsdellite, and as the tetragonal form pyrolusite. The latter is isomorphous with rutile and cassiterite, TiO_2 and SnO_2 . Crystals are rare and have a hardness of 6 to 6.5, with a specific gravity of about 5, and have been called polianite because of the mistaken belief that they were essentially different from the commoner massive varieties. Pyrolusite is usually fine grained, often fibrous or powdery, and thus appears to be soft, as low as 2, and marks paper. Because of the fine-grained nature it may contain adsorbed water. The fine fibrous masses, sometimes radially arranged, are very characteristic. Ores that are mixtures of pyrolusite and other minerals sometimes are called "soft manganese oxides." The soft powdery material, sometimes called wad (*q.v.*), may or may not be pyrolusite; likewise, harder dense material in crusts or nodules may be pyrolusite or may be one of the psilomelane (*q.v.*) type of minerals. Pyrolusite is formed by the alteration of other manganese ores, such as rhodochrosite and rhodonite, and frequently occurs as a pseudomorph after manganite. Black dendritic growths of manganese dioxide are frequently found in limestones and in moss agate quartz.

See also MANGANESE.

(L. S. RL.; X.)

PYROMORPHITE, a mineral with the composition of lead chlorophosphate sometimes occurring in sufficient quantities to be mined as an ore of lead. Pyromorphite results from the alteration of galena (*q.v.*) in the oxidized portions of metalliferous veins and is frequently found in the upper levels of lead mines. The name is from the Greek *pyr*, "fire" and *morphē*, "form"; when a fragment is fused the globule assumes a faceted form on solidifying.

Crystals are common and have the form of a hexagonal prism terminated by the basal planes, often barrel-shaped and sometimes hollow at the ends; globular and reniform masses are also found. The formula is $\text{Pb}_5\text{Cl}(\text{PO}_4)_3$ and all gradations in composition exist between pyromorphite and the isomorphous lead chloroarsenate, mimetite (*q.v.*). The resemblance in external characteristics is so close that as a rule it is possible to distinguish them only by chemical tests. Likewise, it is closely related to vanadinite (*q.v.*), in which the PO_4 is replaced by VO_4 . Pyromorphite is usually bright green, yellow or brown, sometimes orange-red

and rarely colourless and transparent. The lustre is resinous to subadamantine.

The hardness is 3.5 to 4 and the specific gravity about 7.

(L. S. RL.)

PYRONES, a term used in organic chemistry to describe a group of six-membered heterocyclic compounds. Pyrones are of two main types derived from 1:2-pyrone (I) or 1:4-pyrone (II):

these two groups are often described as α -pyrones and γ -pyrones respectively.

Pyrones are not in general degraded by acids, but in some cases show quite a strong basic character and yield oxonium salts with acids. Like esters, pyrones are hydrolyzed by alkali and this reaction is frequently of importance in the determination of their structure. They do not usually show ketonic properties, but possess a stability similar to that of aromatic compounds and may be regarded as heterocyclic analogues of benzene.

The main interest in the chemistry of pyrones has developed from the recognition that quite a large number of naturally occurring organic compounds are derivatives of either α - or γ -pyrones. Thus 6-phenyl-1:2-pyrone (III) has been isolated from cotobark and about 70 natural products are known which are derived from 3:4-benz-1:2-pyrone (coumarin) (IV). Coumarin (*q.v.*) itself (IV) occurs in tonka beans, lavender oil and sweet clover and its pleasant fragrant odour has led to its use in perfumery and in foodstuffs. Umbelliferone (7-hydroxycoumarin) is present in many plants and is obtained by the distillation of the resins from various umbelliferae. Umbelliferone absorbs ultraviolet light and is used in some sun-screen lotions and creams.

Derivatives of 1:4- or γ -pyrone occur very widely in plants and to illustrate the variety of structure which is possible, the structures of chelidonic acid (V) from the lily of the valley and the celandine (*Chelidonium majus*), meconic acid (VI) from opium, maltol (VII) from malted barley and kojic acid (VIII) produced by the growth of the mold *Aspergillus niger* may be compared.

In determining the structure of these natural products advantage is often taken of their reaction with aqueous sodium hydroxide. The following example illustrates the general method. The structure of chelidonic acid (V) was indicated by its alkaline cleavage yielding acetone and oxalic acid. This structure was confirmed synthetically by condensing acetone with diethyl oxalate,

using sodium ethoxide, and then subjecting the intermediate ester ($\text{EtO}_2\text{C} \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CO}_2\text{Et}$) to dehydration and acid hydrolysis.

More complicated derivatives of 1:4-pyrones occur naturally and are probably the most widely occurring oxygen heterocyclic derivatives. They include flavones, *e.g.*, apigenin (IX) from parsley; isoflavones, *e.g.*, irigenin (X) from orrisroot; and xanthonones.

(W. D. Os.)

PYROPHYLLITE, a mineral species composed of hydrous aluminum silicate. It resembles talc (*q.v.*) and has long been used in slate pencils and tailor's chalk. It was carved by the Chinese into small images and ornaments; and has been included with talc under the names pagodite and agalmatolite.

The production and uses of pyrophyllite expanded greatly in the second half of the 20th century. Major uses were in the manufacture of insecticides, ceramics, paint, paper, refractories, roofing, rubber, and plaster products.

The most extensive commercial deposits of pyrophyllite are in the United States in the Deep River region of North Carolina, the leading producing state. Pyrophyllite is also mined in California and in Canada. A massive variety produced in South Africa is marketed under the name of "wonderstone." Pyrophyllite occurs in shear zones in highly metamorphosed acid volcanic rocks. Pale-green foliated masses, very like talc in appearance, are found in the Urals, in Switzerland, and in other localities.

Pyrophyllite is one of the silicates having a sheet structure, like the micas and chlorites. The composition is $\text{Al}_2(\text{OH})_2\text{Si}_4\text{O}_{10}$; it is isomorphous with talc, $\text{Mg}_3(\text{OH})_2\text{Si}_4\text{O}_{10}$, and the two minerals have similar properties as well as uses. Both are soft and have a soapy feeling; pyrophyllite occurs in foliated and massive varieties corresponding to foliated talc and soapstone (steatite).

The folia of pyrophyllite have a pronounced pearly lustre and have a perfect cleavage parallel to their surfaces. They are flexible but not elastic and are usually arranged in fanlike or radiating groups. The foliated variety, when heated, exfoliates and swells up to many times its original volume, hence the name pyrophyllite from the Greek *pyr*, "fire" and *phyllon*, "leaf." The colour of both varieties is white or pale green, grayish or yellowish. The specific gravity is 2.8 to 2.9.

(L. S. RL.; X.)

PYROTECHNICS; see FIREWORKS.

PYROXENE, in mineralogy, the SiO_3 single-chain, or meta-silicate, group of minerals (see SILICON: *The Silicates*). Pyroxenes form one of the principal minerals in many common rock types, such as gabbro, norite, peridotite, pyroxenite, and basalt, and occur as an accessory mineral in some granites, syenites, diorites, and andesites. The pyroxenes are commonly dark-green to black, but in the absence of iron they can be light-coloured to white. The physical aspects of the pyroxenes are characterized by two planes of well-developed cleavages 87° or 93° apart. Except for the sodium-containing varieties, which are usually needlelike, the pyroxenes usually occur as short, stubby, prismatic crystals or mineral grains. Some crystal faces are usually present so that, as the crystal is viewed parallel to the cleavages, the crystal outline is commonly an octagon.

Species.—Mineral names are given to the ideally pure compounds. The naturally occurring minerals usually are composed of mixtures of two or more of the ideal compounds because of the extensive degree to which different metal ions are accepted into the structure of a single crystal. The pyroxenes are subdivided into two groups according to the symmetry of their crystals. Orthorhombic symmetry characterizes the enstatite (MgSiO_3) to orthoferrosilite (FeSiO_3) series. Bronzite and hypersthene are mixtures of enstatite and orthoferrosilite. Monoclinic symmetry characterizes all other pyroxenes, of which diopside, $\text{CaMg}(\text{SiO}_3)_2$; hedenbergite, $\text{CaFe}(\text{SiO}_3)_2$; jadeite or jade, $\text{NaAl}(\text{SiO}_3)_2$; acmite (aegirite), $\text{NaFe}(\text{SiO}_3)_2$; and spodumene, $\text{LiAl}(\text{SiO}_3)_2$; johannsenite, $\text{CaMn}(\text{SiO}_3)_2$; and the clinoenstatite (MgSiO_3) to clinoferrosilite (FeSiO_3) series are representative. The monoclinic pyroxenes augite and pigeonite can be considered as mixtures of the diopside-hedenbergite series with the clinoenstatite-cliniferrosilite series, plus some aluminum.

Spodumene (*q.v.*), as ceramic material and a source of lithium,

and jadeite, as an ornamental stone (see JADE), are the only economically important pyroxenes. Crystals of diopside sometimes have been cut as gem stones.

Formations.—Most of the pyroxenes can be formed over a wide range of temperatures; *e.g.*, enstatite, MgSiO_3 , can be formed theoretically by naturally occurring reactions as low as 95°C . ($\text{MgCO}_3 + \text{SiO}_2 \rightarrow \text{MgSiO}_3 + \text{CO}_2$ at 1 atm. CO_2 pressure) and by other natural reactions as high as $1,557^\circ \text{C}$. Diopside, $\text{CaMg}(\text{SiO}_3)_2$, can be formed theoretically by naturally occurring reactions as low as 135°C . [$\text{CaMg}(\text{CO}_3)_2 + \text{SiO}_2 \rightarrow \text{CaMg}(\text{SiO}_3)_2 + \text{CO}_2$ at 1 atm. CO_2 pressure] and by other natural reactions up to $1,391^\circ \text{C}$. However, in the high-temperature metamorphic, igneous and volcanic environments the stability fields of the pyroxenes are relatively larger and, therefore, pyroxenes are commoner in these environments and are relatively rare in low-temperature environments.

The formation of pyroxene over a wide range of compositional environments is possible because of its ability to accept a large variety of different metal ions into its structure; it is, therefore, found associated with almost any of the other common silicate minerals. Pyroxenes are found in metamorphic, igneous and volcanic rocks as well as in pegmatites, ore deposits, as in the diamond mines of South Africa (see ECLOGITE), and many meteorites.

Chemical Structures.—In terms of chemistry the pyroxenes are characterized by the structure of the Si-O groups in the crystal. The relative ionic sizes of Si^{4+} and O^{2-} are such that Si^{4+} closely fits in the central space between four O^{2-} ions arranged at the corners of a tetrahedron; thus, silicon always surrounds itself with four oxygen ions. Silicon can furnish only four of the necessary eight electrons needed to satisfy the four oxygen ions, and this results in an excess oxygen problem. The various ways in which this oxygen problem is solved form the basis of subdivision of the silicate group of minerals (see also AMPHIBOLE). The pyroxenes are characterized by the following type of solution: If each silicon ion shares two of its four oxygen ions with two other silicon ions, an endless chain results:

The remaining demands of the unshared oxygen ions for one electron each can be satisfied by the formation of bonds with other electron-donating ions. In this manner parallel Si-O chains are bonded together by rows of metal ions parallel to the chains. Almost any of the two-valent metal ions or mixtures of them, or a combination of a three- and a one-valent metal ion, are able to bind the chains together. The difference in the ionic sizes of the metal ions causes slight angular adjustments in the relative position of one Si-O chain to another which result in the two different symmetry classes for the pyroxene group of minerals. Pure nickel, cobalt, zinc or iron pyroxenes or mixtures of them are not known to form, although these elements can be present in small amounts. The reason for the absence of such pyroxenes is that the pyroxene structure becomes unstable in the presence of large amounts of these high bonding energy ions.

For discussion of mineralogical and crystallographic concepts used in this article see MINERALOGY.

See also GEOCHEMISTRY: *Geochemistry of the Lithosphere: Crystallization of Magma*; and references under "Pyroxene" in the Index.

(G. W. DEV.; X.)

PYROXENITE, a rock consisting essentially of minerals of the pyroxene group, such as augite and diopside (a diopside), hypersthene, bronzite or enstatite. Names have been given to members of this group according to their component minerals; *e.g.*, pyroxenite (augite), diallagite (diallage), hypersthene (hypersthene), bronzite (bronzite) and websterite (diallage and hypersthene).

Closely allied to this group are the hornblendites, consisting essentially of hornblende.

PYRRHO or ELIS (*c.* 365–275 B.C.), the Greek philosopher from whom Pyrrhonism takes its name. He had as a teacher

Anaxarchus of Abdera, from whom he learned the view—a one-sided development of the system of Democritus—that every perception and judgment of value is relative. He joined the expedition of Alexander the Great and reached India, where he was able to see for himself, in the fakirs, an example of the total indifference to circumstances for which the Greek philosophers often yearned. About 330 B.C. Pyrrho established himself as a teacher in his native Elis. His reputation spread to other parts of Greece, and later skeptics looked to him as their founder. Other philosophers before him had proclaimed that nothing is known with certainty; Pyrrho seemed to have carried doubt to its logical extreme. He wrote nothing, but some impression of his arguments can be gained from the fragments of the poems of Timon of Phlius. The aim of the wise man is to become imperturbable to the changes of fortune; he must utterly abstain from judgment and be prepared to doubt even sense perception, for it is not the infallible test of truth which others have supposed it to be. However, he must equally not distrust perception on principle, for this would imply that it is known or judged to be false. A placid acceptance of things as they appear, fortitude against pain, and indifference to external fortune seem to be the practical consequences. The skeptics of the New Academy (Arcesilaus and Carneades) professed to derive their skepticism from Socrates, not from Pyrrho (see ACADEMY, GREEK). See also SKEPTICISM.

See L. Robin, *Pyrrhon et le scepticisme grec* (1944). (D. J. A.)

PYRRHOTITE, a mineral species consisting of iron sulfide. Small amounts of nickel and cobalt are often present; the nickeliferous pyrrhotite of Sudbury, Ont., with its associated pentlandite (*q.v.*), is the most important source of nickel. The name is from the Greek *pyr*, "fire," and *rhotes*, "redness." The formula is Fe_{1-x}S , in which x may vary from 0 to 0.2. The variety troilite, having a composition near FeS , has been identified as an important constituent of some meteorites (see METEORITES: *Mineralogical Composition*). Crystals of pyrrhotite have the form of hexagonal plates bounded at their edges by faces of a hexagonal prism and pyramids, which are deeply striated horizontally. More frequently, however, the mineral is massive, with a granular structure. It is magnetic, sometimes with polarity, and is therefore often called magnetic pyrites. The colour is bronze yellow, the lustre metallic, and the streak grayish black. The hardness is 4 and the specific gravity 4.58–4.64. Pyrrhotite occurs in metalliferous veins and as grains and plates disseminated through various rocks. See also NICKEL.

PYRRHUS (319–272 B.C.), king of the Molossians, a people of ancient Epirus, whose costly military successes gave rise to the phrase "Pyrrhic victory." He claimed descent from Pyrrhus or Neoptolemus, the son of Achilles, and was connected with the Macedonian royal house through Olympias, the mother of Alexander the Great. At the age of 12 he became king of Epirus and allied himself with Demetrius I Poliorcetes, who married his sister Deidameia. Dethroned by an Epirote rising in 302, he followed Demetrius to Asia and fought beside him and Antigonus I at the Battle of Ipsus in Phrygia (301). He was then sent to Alexandria as a hostage under the treaty made between Ptolemy I and Demetrius, and there became attached to the king, married his stepdaughter Antigone, and in 297 was by his aid restored to his kingdom; at first he reigned with a kinsman, Neoptolemus II, but soon assassinated him. Pyrrhus now sought to develop his kingdom along Hellenistic lines. In 295 he exploited a dynastic quarrel in Macedonia to obtain the frontier areas of Parauaea and Tymphaea, along with Acarnania, Amphilochoia, and Ambracia; and on Antigone's death he married Lanassa, daughter of Agathocles of Syracuse, receiving Corcyra and Leucas as her dowry. He also married Bircenna, daughter of an Illyrian king, Bardylis, and the daughter of Audoleon, king of Paeonia. Soon he became involved in war with Demetrius, now king of Macedonia, and in alliance with Aetolia heavily defeated his general Pantauchus; two invasions of Macedonia left him king of the western half, with Thessaly, and he relieved Athens from Demetrius' siege. In 285, however, Lysimachus shut him up in Edessa, corrupted his men, and drove him back into Epirus.

In 281 Tarentum, in southern Italy, asked his assistance against

Rome; he crossed with about 25,000 men, and in 280 at Heraclea his cavalry and elephants helped him to win a complete, if costly, victory over Publius Valerius Laevinus. He advanced on Rome through Latium, but the towns were all garrisoned, and Appius Claudius persuaded the Senate to dismiss his minister Cineas with a refusal to negotiate so long as Pyrrhus' troops were in Italy.

In 279 Pyrrhus won another victory, costly to both sides, at Ausculum (Ascoli Satriano) in Apulia; he then crossed to Sicily (278) with the idea of expelling the Carthaginians, who had just allied themselves with Rome. As "king of Sicily" he conquered most of the Punic province except Lilybaeum (Marsala), but his despotic methods provoked a Greek revolt, and in 276 (or early 275) he returned to Italy. In 275 he fought a last battle at Beneventum (Benevento) in which the Romans had a slight advantage, though not the overwhelming superiority claimed by Roman tradition. In consequence Pyrrhus retired to Epirus with a third of his force. In 274 he defeated Antigonus II Gonatas, shutting him up in Thessalonica (Salonika); then, abandoning his newly recovered kingdom of Macedonia, he launched an unsuccessful attack on Sparta to restore Cleonymus (272), and perished the same year in a night skirmish in the streets of Argos.

Pyrrhus was a man of lively and volatile intelligence, an adroit tactician and possessed of a dynamic character; his *Memoirs* and books on the art of war are quoted and praised by many writers, including Cicero; the impression he made on his contemporaries is shown in the many legends that attached themselves to him, but he lacked consistency of purpose and failed to draw profit from his victories, so that his career as a whole was a failure.

PYRROLE. A colourless oil whose existence in coal tar was surmised by the German chemist F. F. Runge in 1834 but which was first isolated and studied by the Scottish chemist Thomas Anderson in 1857. The name is derived from Greek and Latin roots meaning "fiery oil," from the fiery red colour imparted by pyrrole to a wood splint previously moistened with acid. Pyrrole is of great historical interest because of the fact that one of its derivatives, indole (*q.v.*), is the fundamental building block of the regal dye of the ancients, Tyrian purple, as well as of the most important ancient and medieval dye, indigo. Pyrrole is also the structural unit of chlorophyll, the green portion of the pigment of leaves; of heme, the red portion of the pigment of blood; of the pigments of the bile; and of the pigments of numerous types of bacteria, algae and other living organisms. Pyrrole pigments are found in coal, petroleum and similar substances derived from plant and animal sources.

The colouring matters derived from pyrrole are the objects of extensive scientific investigations because their functions in plants and animals are so critically important to life. Atmospheric carbon dioxide, fixed by photosynthesis involving chlorophyll, is the ultimate source of most of our food and fuel, and the efficiency of transportation of oxygen by the blood pigment hemoglobin is indispensable to the rapid motions of higher animals. In addition, these pyrrole pigments are probably produced by living organisms in greater tonnage than any other class of pigments. Derivatives of pyrrolidine, which is completely reduced pyrrole occur in alkaloids, such as cocaine and nicotine, and as building blocks of proteins in the form of the amino acids proline, hydroxyproline and tryptophan.

Pyrrole boils at 131° C., is slightly lighter than water (density 0.9669) and has the composition $\text{C}_4\text{H}_5\text{N}$. It is sparingly soluble in water but dissolves in alcohol, ether and many other solvents. Its structural formula was assigned correctly by the German chemist Adolf von Baeyer in 1870 in the course of his classical investigations on the structure of indigo. It is conventionally represented as in diagram I; diagram II is the formula for pyrrolidine:

Pyrrole is characterized by great chemical reactivity, being slowly destroyed by air with the formation of a brown pigment. It is also destroyed by strong acids, being partially converted into indole, and it enters into combination with a wide variety of chemical reagents. It has been obtained from bone oil and by destructive heating of proteins but is now available commercially from acetylene, formaldehyde and ammonia. Pyrrole is moderately toxic, acting as a nerve poison. Certain of its derivatives have found a limited application in medicine. Their main use is in organic chemical synthesis for the study of the structure and functions of the naturally occurring pigments. The most important pyrrole derivatives are the porphyrins (from the Greek for purple) and the chlorines (from the Greek for yellow-green) and their metallic compounds. A typical iron-porphyrin compound is hemin, the oxidized form of the coloured portion of the blood pigment.

See Hans Fischer and Hans Orth, *Die Chemie des Pyrrols* (1934-40). (A. H. CN.; X.)

PYRUVIC ACID, CH_3COCOOH , is an organic acid that probably occurs in all living cells. It ionizes to give a hydrogen ion and an anion termed pyruvate. Biochemists use the terms pyruvate and pyruvic acid almost interchangeably.

Pyruvic acid is a key product at the crossroads between the catabolism (breaking down) and anabolism (synthesizing) of carbohydrates, fats, and proteins (see **METABOLISM: Intermediary Metabolism**). A complex sequence of enzyme reactions leading from sugar (or carbohydrate, in the form of glucose or fructose) to pyruvate is common to five metabolic processes. These are: (1) the fermentation of sugar to ethyl alcohol by yeast; (2) the fermentation of sugar to lactic acid in muscle (for these two processes see **FERMENTATION: The Modern Position**); (3) the oxidation of sugar to carbon dioxide and water by way of the Krebs cycle (*q.v.*); (4) the conversion of sugar to fatty acids; and (5) the conversion of sugar to amino acids, such as alanine, which are the building blocks of proteins.

Pyruvic acid, formerly called pyroracemic acid, was first obtained by J. J. Berzelius in 1835 by the dry distillation of tartaric acid. The preparation of pyruvic acid in bulk amounts is similar: tartaric acid is heated with fused potassium hydrogen sulfate at $210^\circ\text{--}220^\circ\text{C}$. The product is purified by fractional distillation under reduced pressure. At room temperature pure pyruvic acid is a colourless liquid with a pungent odour resembling that of acetic acid. On cooling, it forms crystals that melt at 13.6°C . The boiling point is 165°C .

PYTHAGORAS (fl. 5th century B.C.), a noted Greek sculptor of Rhegium (present Reggio di Calabria), a contemporary of Myron and Polyclitus and their rival in making statues of athletes. One of these, that of the boxer Euthymus of Locri, was erected after the latter's third victory at Olympia in 472 B.C. Pythagoras was born at Samos and migrated in his youth to Rhegium, in Italy. He made a statue of Philoctetes noted for the physical expression of pain, an Apollo shooting the Python at Delphi, and a man singing to the lyre. His technical improvements went far in ending archaic stiffness. No existing work can be certainly attributed to him, and, although his influence must have been widespread, attempts to identify copies of his works remain conjectural.

PYTHAGORAS AND PYTHAGOREANISM. The Greek philosopher Pythagoras, who was active c. 530 B.C. and gave his name to an order of scientific and religious thinkers, was born in Samos. Reputed by legend to have traveled extensively, he was certainly in contact with ideas native to Asia Minor. The historically important part of his career began with his migration to Crotona, a Dorian colony in southern Italy, about the year 529.

According to tradition, Pythagoras was driven from the Aegean island of Samos by the tyranny of Polycrates. At Crotona he became the centre of a widespread organization which was, in its origin, a religious brotherhood or an association for the moral reformation of society rather than a philosophical school. The Pythagorean brotherhood had much in common with the Orphic communities which sought by rites and abstinences to purify the

believer's soul and enable it to escape from the "wheel of birth." Although its aims may have been primarily those of a religious order rather than a political league, it actively supported aristocracies. Indeed it gained control over many Western Greek colonies; and it was politics which led in the end to the dismemberment and suppression of the society. The first reaction against the Pythagoreans, led by Cylon, brought about the retirement of Pythagoras to Metapontum, where he remained until his death at the end of the 6th or the beginning of the 5th century.

The order appears to have continued powerful in Magna Graecia until the middle of the 5th century B.C. when it was violently trampled out, its meetinghouses being everywhere sacked and burned. Those Pythagoreans who survived took refuge abroad: Lysis went to Thebes in Boeotia, where he became the instructor of Epaminondas; and Philolaus (*q.v.*), who according to tradition wrote the first exposition of the Pythagorean system, also lived at Thebes at the end of the 5th century. Philolaus, however, and some others were afterward able to return to Italy. Tarentum (Taras) then became the chief seat of the school: Archytas (*q.v.*), the friend of Plato, was prominent there both as a philosopher and as a statesman in the first half of the 4th century B.C. About the middle of that century, however, the Pythagoreans disappeared as a philosophic school.

Philosophical Beliefs.—There seems to have been a split in the school, dating from about the middle of the 5th century B.C. On the one hand, there were "the mathematicians," represented by such names as Archytas and Aristoxenus (*q.v.*), who were interested in scientific studies, particularly in mathematics and in musical theory; on the other, there were the more conservative members of the school, who concentrated on the moral or religious precepts and were called *akousmatikoi* (from *akousmata*, "oral traditions"). It is probable that both the scientific and the religious elements were present from the start in Pythagoreanism. Most of the evidence for the beliefs of Pythagoras himself is doubtful. It was customary for his later disciples to claim the master's authority indiscriminately; and Aristotle speaks only vaguely of "the so-called Pythagoreans," "the Italians," and so on. The doctrines that can reasonably be attributed to Pythagoras may, however, be summarized as follows:

1. First and foremost is Pythagoras' account of the soul. He believed in the transmigration of the individual soul from one body to another, even of a different species. "Do not hit him," he once said to a man who was beating a puppy, "it is the soul of a friend of mine. I recognized it when I heard it cry out." But if a man led a pure life, his soul might be released from all flesh. It is possible that this held good only for the exceptional man, a seer such as Pythagoras himself or Empedocles (*q.v.*). But the view of the body as the tomb or prison of every soul, with philosophy as the meditation of death and the release from the body, seems to be attributed to a Pythagorean in Plato's *Phaedo* (61 D ff.). Its importance in the history of religion need not be underlined. All this must be set in the framework of the belief, brought to the Greeks from Asia Minor, which ascribed to souls a future life in the starry heavens. For nearly all Pythagoreans the actual composition of the soul (*e.g.*, out of fire or air, the warmth or breath of life) gave it a natural affinity with the stars or the sky.

2. The pure life consisted in obeying precepts which are mostly recognizable as primitive taboos; *e.g.*, not to eat beans, not to poke a fire with iron. More strictly moral were the three questions which had to be put to oneself every evening: In what have I failed? What good have I done? What have I not done that I ought to have done? Of external aids to purification one of the most important was music.

3. The fascination of numbers for the school must go back to its founder. Pythagoras' greatest discovery was probably the dependence of the musical intervals on certain arithmetical ratios of lengths of strings at the same tension, 2:1 giving the octave, 3:2 the fifth and 4:3 the fourth. It must have contributed powerfully to the idea that "all things are numbers." Though not necessarily to be attributed to Pythagoras, this idea was the philosophical kernel of Pythagoreanism. Early forms of it probably did not distinguish between things being numbers, having numbers,

and merely resembling them. But in Aristotle's account of it (*Metaphysics*, i, ch. 5 and 8) numbers were the elements of everything, in the way that fire, water, etc., had been for other thinkers.

The whole heaven formed a "musical scale and number"; and even such things as reason, justice and marriage were identified with distinct numbers. The elements of numbers themselves were "the odd" and "the even" or "limit" and "the unlimited," which in Aristotle's view represent a primitive insight into the notions of form and matter. These two pairs headed a list of ten pairs of fundamental "opposites," the remaining eight being "one" and "many," "right" and "left," "male" and "female," "rest" and "motion," "straight" and "curved," "light" and "darkness," "good" and "evil," "square" and "oblong." It was a philosophy of metaphysical and moral dualism: but it came to see the universe as a harmony of opposites, in which "the one" generated the number series, or "limit" successively imposed itself on "the unlimited."

Thus music and the belief in a stellar heaven (especially if this had originally been associated with Babylonian astrology) are two links between the religious content of Pythagoras' outlook and the mathematical and astronomical studies made later by the scientific wing of his school. The first to have made a comprehensive system may have been Philolaus. Thereafter the three doctrines outlined above would have been common to the *akousmatikoi* and to the "mathematicians" alike. Their development by the latter can be seen in what follows. Much of it, as Otto Neugebauer, for instance, points out (*The Exact Sciences in Antiquity*, 1952), had been known to the Babylonians.

Pythagorean Arithmetic.—The unit or 1 (which was not strictly a number) was assigned or equated to the point, 2 to the line, 3 to surface, and 4 to solid. The assertion of J. Burnet and many others, that numbers were regularly held to be spatially extended, is open to question. The normal account seems to have been that the point "flowed into" the line, the line into surface, and so on. But numbers were certainly represented by arrangements of pebbles in triangles, squares, etc.; and the practice assisted the geometrical expression of arithmetical theorems, which was due fundamentally to the existence of both rational and irrational fractions, since these contradicted the strict definition of numbers as magnitudes. The holy tetractys, by which the later Pythagoreans

used to swear, was a figure of this kind . . . representing the

triangular number 10 and showing at a glance its composition as $1 + 2 + 3 + 4$. To add a row of five dots gives the next triangular number with 5 as the side, and so on, showing that the sum of any number of the series of natural numbers beginning with 1 is a triangular number. The sum of any number of the series of odd numbers beginning with 1 is similarly seen to be a square; thus

3 and 5 added successively to 1 give figures of the kind 

called gnomons. If we take the series of even numbers, we see that the sum of any number of them beginning with 2 makes an

oblong number 

The successive odd numbers after 1 were themselves called gnomons because the addition of each to the sum of the preceding ones (beginning with 1) makes a square number into the next larger square. If the gnomon added to a square is itself a square number, there is a square number which is the sum of two squares; thus $1 + 3 + 5 + 7 = 16$ or 4^2 , and the addition of 9 ($= 3^2$) gives 25 or 5^2 , that is, $3^2 + 4^2 = 5^2$. Pythagoras himself is credited with a general formula for finding two square numbers the sum of which is also a square, namely (if m is any odd number), $m^2 + \{\frac{1}{2}(m^2 - 1)\}^2 = \{\frac{1}{2}(m^2 + 1)\}^2$. This connects itself with the theorem of the square on the hypotenuse of a right-angled triangle, which tradition universally associates with the

name of Pythagoras. In the case of the isosceles right-angled triangle the ratio of the hypotenuse to either of the other sides is what is written as $\sqrt{2}$, which is irrational in the sense that its value cannot be expressed exactly as a ratio between numbers. The Pythagoreans not only perceived the irrationality of $\sqrt{2}$ but also developed the method of finding ever closer approximations to the value of $\sqrt{2}$ by forming the series of the so-called side and diagonal numbers that satisfy one or other of the two equations $2x^2 - y^2 = +1$ and $2x^2 - y^2 = -1$, when x stands for the length of one of the equal sides and y for that of the hypotenuse. The method depends on the proposition $2x^2 - y^2 = (2x + y)^2 - 2(x + y)^2$, whence it follows that, once one set of values for x and for y has been found such that $2x^2 - y^2 = +1$, then $2(x + y)^2 - (2x + y)^2 = -1$, the higher numbers $x + y$ and $2x + y$ in the latter equation taking the place of the x and of the y in the original; then, vice versa, with the higher numbers substituted, we may proceed from $2x^2 - y^2 = -1$ to $2(x + y)^2 - (2x + y)^2 = +1$, where $x + y$ and $2x + y$ stand for a second set of higher numbers; and so *ad infinitum*. Hence is derived the infinite series $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \frac{7}{2}, \frac{9}{2}, \frac{11}{2}, \frac{13}{2}, \frac{15}{2}, \dots$ giving progressive approximations to $\sqrt{2}$.

Contributions to Geometry.—Other contributions to geometry were made by the Pythagoreans. In the first place Pythagoras, it is said, himself formulated definitions in geometry. Secondly, the Pythagoreans proved that the sum of the three angles of any triangle is equal to two right angles: there is their proof, which, like Euclid's, uses the property of parallels; hence they knew the theory of parallels. Thirdly, they discovered the powerful method in geometry of the application of areas (*cf.* Eucl. i, 44, 45), including application with excess and defect (*cf.* Eucl. vi, 28, 29), which amounts to the geometrical solution of any quadratic equation in algebra having real roots. Fourthly, they discovered the theory of proportion, together with the arithmetic, the geometric and the harmonic means. The theory and the arithmetic

mean appear in the middle terms of the proportion $a : \frac{a+b}{2} = \frac{2ab}{a+b} : b$, a particular case being $12:9 = 8:6$, from the terms of

which the three musical intervals can be obtained. The Pythagorean theory of proportion was arithmetical (after the manner of Euclid, book vii) and did not apply to incommensurable magnitudes; it must not therefore be confused with the general theory due to Eudoxus, which is expounded in Euclid v. Fifthly, it was claimed that Pythagoras discovered the construction of the five regular solids. It was more probably Theaetetus who (as we read elsewhere) discovered the octahedron and the icosahedron; but the Pythagoreans were clearly acquainted with the pyramid or tetrahedron and the dodecahedron. The construction of the dodecahedron requires that of a regular pentagon, which again depends (as in Eucl. iv, 10, 11) on the problem of Eucl. ii, 11, about the division of a line in extreme and mean ratio, a particular case of the application of areas. The assumption that the Pythagoreans could construct a regular pentagon is confirmed by the fact that the pentagram, the triple interwoven triangle, or the star-pentagon, was used as a symbol of recognition between the members of the school and was called by them health. Sixthly, the Pythagoreans discovered how to construct a rectilinear figure equal to one and similar to another rectilinear figure.

To sum up, it may be said that Pythagorean geometry covered the bulk of the subject matter of Euclid's books i, ii, iv, vi (and probably iii), with the qualification that the Pythagorean theory of proportion was inadequate in that it did not apply to incommensurable magnitudes.

Pythagorean Astronomy.—Pythagoras was one of the first to hold that the earth and the universe are spherical in shape. He appreciated that the sun, the moon and the planets have a motion of their own independent of the daily rotation and in the opposite sense. It is improbable that Pythagoras himself was responsible for the astronomical system known as Pythagorean, which deposed the earth from its place in the centre and made it a planet like the sun, the moon and the other planets; for Pythagoras apparently the earth was still at the centre.

The later Pythagorean system is attributed alternatively to Philolaus and to Hicetas, a native of Syracuse. The system may be thus described. The universe is spherical in shape and finite in size. Outside it there is infinite void, which enables the universe to breathe, as it were. At the centre is the central fire, wherein is situated the force which directs the movement of the universe. Within the universe bodies revolve around the central fire as follows: nearest to the central fire is the counterearth, which always accompanies the earth; next in order (reckoning from the centre outward) is the earth, then the moon, then the sun, then the five planets and then, last of all, the sphere of the fixed stars. The counterearth, revolving in a smaller orbit than the earth, is not seen by us because the hemisphere in which we live is always turned away from the counterearth. This part of the theory involves the assumption that the earth rotates about its own axis in the same time as it takes to complete its orbit around the central fire; and as the latter revolution was held to produce day and night, it is a fair inference that the earth was thought to revolve around the central fire in a day and a night, or in 24 hr. The counterearth may have been invented to explain the comparative frequency of lunar eclipses. The system amounts to a first step toward an anticipation of the Copernican hypothesis, and Copernicus himself referred to it as such.

Later Pythagoreanism.—A survival of Pythagorean practices and doctrines, particularly that of immortality, is attested in Rome from the 1st century B.C. As a philosophical theory this Neopythagoreanism (*q.v.*) merged with Platonism. But it was also a kind of cult; and the frescoes in the underground basilica of the Porta Maggiore have been claimed as Pythagorean. In imperial times there were Pythagoreanizing philosophers and mathematicians in Alexandria, in Syria, and elsewhere. Plato's immediate successors had already made a partial return to more purely Pythagorean theory; and Neoplatonists, such as Iamblichus in the 4th century A.D., drew on them as well as on more recent, forged Pythagorean writings (*e.g.*, the *Orphic Hymns*).

For Christian Fathers, such as Ambrose, Pythagoras was an authoritative figure because he was thought to have been a Jewish intermediary between Moses and Plato. By the 16th century he was liable to be reckoned, and his beliefs cited, according to the interests of the writer, as a poet, as a magician, as the father of the Cabala, as a mathematician, or as a champion of the contemplative life. He is depicted, characteristically an old man, among the philosophers, in Raphael's "School of Athens."

Alleyne, vol. 1 (1881); J. Burnet, *Early Greek Philosophy*, 4th ed. (1930) and *Greek Philosophy, part 1, Thales to Plato* (1914); T. L. Heath, *History of Greek Mathematics*, vol. 1 (1921), and, for astronomy, *Aristarchus of Samos* (1913); B. L. Van der Waerden, *Science Awakening*, Eng. trans. by A. Dresden (1954); and S. Dill, *Roman Society from Nero to Marcus Aurelius* (1904). (T. L. H.; A. C. Lo.)

PYTHEAS OF MASSALIA (Marseilles), Greek explorer and geographer of c. 300 B.C., was the first Greek to visit and describe the Atlantic coast of Europe (including Britain). His main work, *On the Ocean*, is lost; citations in later authors do not give a coherent picture of it or even show exactly how far he traveled. There is one fragment of a second work, perhaps a complementary description of the Mediterranean coast of Europe. Pytheas' writings were extensively used by later geographers, notably Eratosthenes and Poseidonius; but he was attacked as a Munchausen by equally eminent men, particularly the historian Polybius (followed by Strabo). Modern scholars have rehabilitated him, often to excess. He certainly visited some northern countries, and his comments on small points, *e.g.*, on the native drinks made from cereals and honey and on the use of threshing barns (contrasted with open-air threshing in the Mediterranean sun), show acute observation. His scientific interests appear from his calculation of the ratio of the hand of a sundial to its shadow at the summer solstice, and from his notes, sometimes rather puzzling, on the length of the longest day as he traveled northward. These ob-

servations were used by his successors (not, it seems, by Pytheas himself) for establishing parallels of latitude. He also noticed that the Pole star is not at the true pole and that the moon affects the tides.

Pytheas is at his worst in giving measurements, whether in days' journeys (five from Cadiz to Cape St. Vincent, three from Ushant to the French coast) or in stadia (40,000, *i.e.*, over 4,000 mi., for the circumference of Britain). His Thule—the northernmost inhabited island, six days' sail from northern Britain and extending at least to the Arctic circle—cannot be identified. It may be Norway (but not Iceland).

Pytheas was too ready to believe what he was told: the story of the Stagnant sea bounding the earth in the far north—a mixture of earth, air and water, like a "sea-lungs" (jellyfish?)—deserves Polybius' ridicule. His work laid a valuable foundation for greater men, though, as Polybius saw, he often misled them.

(E. BA.)

PYTHIUS (PYTHIOS, PYTHEOS), noted Greek architect of the 4th century B.C. With the architect Satyrus he built the great Mausoleum at Halicarnassus (353 B.C.), one of the seven wonders of the world, ordered by Queen Artemisia as a tomb for her husband, Mausolus. A number of restorations of the mausoleum were made in the 19th century. Pythius cultivated the Ionic style, in which he also constructed the temple of Athena at Priene. The dedicatory inscription, which is in the British museum, records that the founder was Alexander the Great. Pythius is mentioned by Pliny and Vitruvius.

PYTHON, the common name for a subfamily (Pythoninae) of large nonpoisonous, constricting snakes of the boa family (Boidae). The largest genus, *Python*, is found throughout the tropics of the Old World. Pythons are sometimes given family rank as the Pythonidae. They are distinguished from the boas, with which they are often confused, in certain skull characteristics (presence of a supraorbital bone) and in the habit of laying eggs instead of bringing forth young alive. As in the boas, vestiges of the hind limbs are present, visible externally as a pair of claws adjacent to the anal cleft. The teeth are strong and adapted for catching and holding prey. There is no venom or venom-conducting apparatus.

Killing of the prey is effected by constriction: one or more coils of the body are thrown around the victim, and pressure is applied by the powerful body muscles. Although the pressure exerted by a large python is considerable, the prey is killed by suffocation rather than by any actual crushing of the ribs. A python, like other constrictors, takes advantage of the struggles of its prey by tightening its coils each time the captive exhales. During the swallowing process much saliva is secreted, and should the prey be disgorged, as may happen if the snake is disturbed, it will be found to be covered with this secretion. This evidently accounts for the fable that pythons cover their prey with saliva before swallowing it.

Large pythons may be strong enough to kill an animal the size of an ox, but stories of their killing and eating cattle and horses are not to be credited. The prey is swallowed whole, and though the mouth is greatly distensible, it cannot be stretched beyond the calibre of a moderate-sized pig. Authentic accounts of attacks on man are extremely few.

Most pythons are partly arboreal and are likely also to be found lying quietly in water. Reproduction is by means of leathery shelled oval eggs, of which there may be a hundred or more in a clutch. The eggs are laid in a heap and are guarded by the mother, who coils herself around them.

The largest species is the reticulated or regal python (*Python reticulatus*) of the Malay region, which occasionally reaches a length of 30 ft. The Indian python (*P. molurus*), up to 25 ft. long, is frequently seen in zoological gardens, as is the African rock python (*P. sebae*). Other members of the python group include the remarkable arboreal green python of New Guinea (*Chondropython viridis*) and various other Australasian types. *Loxocemus*, a genus of smaller snakes of southern Mexico and Central America, is doubtfully placed in the subfamily; some assign these dwarf "pythons" to the family Xenopeltidae. See also SNAKE.

(K. P. S.; X.)

PYTHON, in Greek mythology a huge serpent which was killed by Apollo at Delphi because it would not let him found his oracle, being accustomed itself to give oracles, or, according to another version of the story, because it had persecuted his mother Leto during her pregnancy. In the earliest account (the Homeric Hymn to Apollo) the serpent is nameless and female, but later it is male and named Python (Pytho being the old name for Delphi). Python was generally said to be the child of Gaea

(Earth), who traditionally had an oracle at Delphi before Apollo came. The Pythian Games held at Delphi in historic times were supposed to have been instituted by Apollo to celebrate his victory over Python. In Hellenistic Greek the name Python became a common noun meaning the power of divination possessed by certain persons; *e.g.*, by the woman in Acts 16:16. See also

ORACLE.

See J. Fontenrose, *Python* (1959).

Q THIS letter corresponds to Semitic **ק** (*koph*), which may derive from an earlier sign representing the eye of a needle, and to Greek **Ϟ** (*koppa*). The form of the majuscule has been practically identical throughout its known history. In the form found on the Moabite stone the vertical stroke extended to the top of the loop, and the same is the

case with an early form **ϙ** from the island of Thera. The Etruscan form was identical with the Greek. The Latin alphabet had two forms, **Q** and **Q̄**.

In the minuscule form the stroke has moved to the right side of the letter owing to the speed of writing. This produced the cursive form **q** occurring in the 6th century A.D. Uncial writing also had the form **q** and the Carolingian form was practically identical.

In Semitic the sound represented by the letter was an unvoiced guttural pronounced farther back than that represented by the letter *kaph*. In Greek the letter was largely redundant, and in the eastern alphabet was entirely superseded by *kappa*. In the Chalcidic alphabet, however, it lingered and spread from there, probably through the Etruscan, into the Latin alphabet, where it was used only with a following *u*, the combination representing the unvoiced labiovelar sound in such words as *quaero*. The combination of these two letters holds to the present day, and in modern English *q* is not used unless followed by *u*, even if, in words such as "oblique," the sound is a simple velar and not a labiovelar. The most usual position of the sound is initial in words such as "queen," "quick." *Q* is used apart from *u* only very rarely in words of foreign origin, especially to represent a Semitic guttural, as in "Qabala," "Iraq." See also ALPHABET.

(B. F. C. A.; J. W. P.)

QADI (**KADI**, **CADI**), a judge in a Muslim court where decisions are rendered according to the canon law of Islam (*shari'a*). Theoretically his jurisdiction embraces both civil and criminal matters, but in practice the qadi hears cases that pertain to religion—e.g., those involving inheritance, pious bequests (*awqaf*), marriage and divorce. Usually there have been other courts and officials to deal with the remaining areas of law. Generally the qadi's work was restricted to arbitrating disputes and rendering judgments in matters brought before him and did not include the administrative side of law. Eventually, however, he acquired additional duties such as the management of pious bequests, guardianship of property for orphans, imbeciles and others incapable of overseeing their own interests, and control of marriages for women without guardians. The qadi's decision in all matters was final.

Since the qadi performed an essential function in early Muslim society, requirements for the post were carefully stipulated in Muslim law books. A qadi must be a male of full adult age, a Muslim, who had the status of a free man. Women, minors, slaves and non-Muslims all had an inferior position under the canon law and could not become qadis. Also, he must be a man of good character, possessing a sound knowledge of the canon law. In the first Muslim centuries (7th and 8th centuries A.D.) it was held that the qadi must even be capable of deriving the specific rules of law from their sources in the Koran, the tradition of the prophet and the agreement of the community. In time, however, this view was displaced by another which bound the qadi to accept absolutely the opinions of one of the founders of the four orthodox Muslim law schools. Finally, a qadi must have good vision and hearing and be able to read and write.

The caliph Omar, second in succession to Mohammed, was the first to have appointed a qadi to relieve himself of the necessity of judging every dispute that arose in the community. Thereafter, it was considered a religious duty upon the authorities in every place to provide for the administration of justice through the appointment of qadis. (C. J. A.)

QAIS (**JAZIREH-YE QEYS**), an island in the Persian Gulf lying about 10 mi. (16 km.) off the mainland of Iran in latitude 26° 32' N and longitude 54° E, is the site of a trade centre of great importance in former times. Pop. (1954) 1,686. The island, measuring 9 by 5 mi., rises 120 ft. (37 m.) above sea level to a plateau and is bare of vegetation except for small patches of cultivation and a few date groves and stunted herbage. It is surrounded by a reef and pearl banks.

In the early Muslim period Qais formed a part of the province of Fars, but it was only in the later Middle Ages that it attained importance, when a prince of south Arabian origin obtained possession of it, built a fleet there, and gradually extended his power. He captured Siraf (modern Taheri), northwest of Qais on the mainland, which was then the principal market of the Persian-Indian-Chinese trade. In the first half of the 11th century Siraf was gradually deserted, and finally Qais supplanted Siraf.

At its period of greatest power, the dynasty of Qais also ruled over the district of Oman on the opposite Arabian shore. The Rabbi Benjamin of Tudela, Spain, visited Qais between A.D. 1164 and 1173, and noted the rich market of the island whose chief business was the exchange of Persian, Mesopotamian, Arabian, and Indian manufactures and produce. The site of the old city is marked by the ruins known as Harirah on the north coast. Qais in turn lost its importance—for reasons not known—in the 14th century, and its trade passed to Hormuz. (P. Z. C.; H. Bo.)

QAJAR (**KAJAR**, **KADJAR**) **DYNASTY**, the ruling dynasty of Persia from 1794 to 1925. Its founder was Agha Mohammed Khan, chief of the Asterabad branch of the Qajars, a powerful tribe of Turkmen origin. Although not crowned until 1796, Agha Mohammed Khan had been in effective control of Persia since the death in 1794 of Lutf Ali Khan, the last of the Zand dynasty. On his assassination in 1797 Agha Mohammed Khan was succeeded by his nephew Fath Ali, to gain whose favour France and Great Britain made strenuous efforts early in his reign. Fath Ali Shah fought two disastrous wars with Russia, losing Georgia, Armenia, and northern Azerbaijan. His grandson Mohammed, who succeeded him in 1834, came much under the influence of Russia. He made two unsuccessful attempts to capture Herat. When he died in 1848 the succession devolved upon his son Nasir ad-Din (*q.v.*), who proved to be the ablest and most accomplished of the Qajar sovereigns. During his reign European science and methods of education were introduced into Persia and one of the factors in the modernization of the country was the introduction of the telegraph in 1859. When Nasir ad-Din Shah was assassinated by a fanatic in 1896, the crown passed to his son Muzaffar ad-Din, the chief feature of whose reign was the granting of a constitution in 1906. Dying early in 1907, he was succeeded by his son Mohammed Ali who attempted, with the aid of Russia, to rescind the constitution and abolish parliamentary government. In so doing he aroused such opposition that he was deposed (1909), his place on the throne being taken by his 11-year-old son Ahmad Mirza. The new monarch proved to be effete, pleasure-loving, and incompetent. On Oct. 31, 1925, while he was absent in Europe, the *majlis* (national consultative assembly) declared that the rule of the Qajar dynasty was terminated. See also PERSIAN HISTORY. (L. Lo.)

QALYUBIYAH, AL, in the United Arab Republic, is the smallest of the Egyptian delta *muhafazat* (governorates), immediately north of Cairo and at the apex of the Nile Delta. It is bounded northeast by Ash Sharqiyah *muhafaza*, east by the Arabian (Eastern) desert, and west by the Damietta branch of the Nile after its bifurcation at Al Khayriyah (Delta) barrage. Area 364 sq.mi. (944 sq.km.). Pop. (1960) 988,055. The capital is Banha (*q.v.*) in the northwest between the Nile and the Tawfiqi Canal near the ancient Athribis. There the bridge over the Nile carries the main railway from Cairo to Alexandria.

The *muhafaza* is one of the most heavily populated of the delta (average density 2,060 persons per sq.mi.) with about 60% of the population relying upon agriculture for their livelihood. Farm-

land is irrigated mainly from the Tawfiqi Canal (paralleling the Nile) and the Ismailia Canal to the east. The principal crops in order of importance are maize (corn), cotton, wheat, and clover. The proximity of the large market centre of Cairo has encouraged the expansion of acreage under market gardening and orchards. There are no mineral resources other than local deposits of basalt at Abu Za'bal on the eastern fringe of the cultivated zone. The principal towns are Banha and Qalyub. (A. B. M.)

QARO (CARO or KARO), **JOSEPH BEN EPHRAIM** (called MARAN, "our master") (1488–1575), codifier of Jewish law (*halakha*), whose code is still authoritative for Orthodox Jewry, was born in Spain. As a child he shared in the expulsion of the Spanish Jews (1492), and migrated from place to place till 1536, when he settled in Safed (Safad), Palestine, then the centre of both talmudic learning and cabalistic mysticism. There he spent the rest of his life.

In learning and critical power, Qaro was second only to Maimonides in the realm of Jewish law. In face of the disintegration in Jewish life caused by the Spanish expulsion, Qaro felt called upon to systematize the laws and customs of Judaism. This he attempted to do in two great works. The earlier and greater of these was in the form of a commentary entitled *Beth Yosef* ("House of Joseph," published 1550–59) on the *Arb 'ah Turim* of Jacob ben Asher (*q.v.*), designed exclusively for specialists. In it Qaro shows an astounding mastery of the Talmud and the legalistic literature of the Middle Ages. But the *Beth Yosef* is by no means systematic. Systematization was effected in Qaro's second work, the *Shulhan 'Arukh* ("The Well-Laid Table"), in its original form an extract from the *Beth Yosef*. Finished in 1555, it was published in four parts at Venice in 1565. The work, which showed a certain prejudice in favour of the Sephardic view, was at first received with some hostility by the Ashkenazic Jews. But after 1578, when it was first published together with Moses Isserles' commentary (see ISSERLES, MOSES BEN ISRAEL) covering Ashkenazic practice, it gradually became the almost unquestioned authority of the whole Jewish world, and it remained so until the advent of Reform in the 19th century.

The influence of the *Shulhan 'Arukh* was to some extent pernicious. It put Judaism into a straitjacket, inhibiting independence of judgment; the code stood in the way of progressive adaptation of Jewish life to the life of Europe. But its good effects far outweighed the bad. It sanctified the home, it dignified common pursuits. It was a bond of union, a bar to latitudinarianism, an accessible, easily understandable guide to ritual, ethics, and law.

Parts of the *Shulhan 'Arukh* are available in English translation: H. E. Goldin's translation of S. Ganzfried's abridgment, *Code of Jewish Law* (1927); and C. N. Denburg's translation (including Isserles' glosses) of the second and fourth parts, *Code of Hebrew Law*, 2 vol. (1955).

See R. J. Zwi Werblowsky, *Joseph Karo, Lawyer and Mystic* (1962).

QASIM, AL, a district of northern Najd (*q.v.*), Saudi Arabia, lying athwart the middle course of the Wadi ar Rummah (Rimah). It has a settled population of about 200,000; the main centres are Buraydah (*q.v.*) and 'Unayzah. Formerly an area of contention between Ibn Rashid (who had Turkish support) and Ibn Saud, it was recovered by Ibn Saud in 1904 and has remained peaceful. By the 1960s much progress had been made in developing its water resources and agriculture. (H. St. J. B. P.; X.)

QATAR, a sheikhdom under British protection on the west coast of the Persian Gulf. It occupies a desert peninsula (100 by 50 mi. [160 by 80 km.]) east of Bahrain, and borders on the south Saudi Arabia and Trucial Oman, with both of which its boundaries are disputed but remain *de facto*. Pop. (1964 est.) 60,000. The capital is Ad Dawhah (Dauha, Doha) on the east coast, once a centre of pearling activity, which declined substantially. Oil, discovered at Dukhan on the west coast in 1939, was brought into production in 1946. Output was declining from a peak of nearly 9,000,000 tons a year in the early 1960s and yielding Qatar an income of about £18,500,000. One quarter of the revenue is reserved for the ruler; the rest is used on public development and welfare. Free education and health services and hospitals are provided, the drinking water supply has been doubled, and two power stations

built. In 1960 and 1961 oil was found offshore.

The British political agent and the sheikh's British adviser reside at Ad Dawhah. Various shipping lines visit Musay'id (Umm Sa'id), the oil port on the east coast, and there is regular air service between Ad Dawhah, Sharjah, Bahrain, and Beirut. The population, mainly concentrated in the three centres of Dukhan, Musay'id, and Ad Dawhah, has a sprinkling of Bedouin and semi-Nomadic elements, and Indian and Pakistani nationals.

For long Qatar was under Persian rule, and paid Rs. 3,000 a year to the governor of Bushire for the right to fish for pearls. It became independent of Persia in the 19th century under Thani, the founder of the Al Thani dynasty; he was succeeded by his son Mohammed, who in 1868 signed an agreement with Great Britain. Mohammed's son Qasim died in 1913 at the age of 111 years, and his son 'Abdullah renewed the 1868 agreement with Britain in 1916. He was succeeded in 1949 by 'Ali bin 'Abdullah, who in October 1960 abdicated in favour of his son Sheikh Ahmed bin 'Ali. The sheikh is an absolute monarch. (H. St. J. B. P.; X.)

QAYEN (QAIN), a town and *bakhsh* (subdistrict) in the southern highland (Kuhistan) region of the *ostan* (province) of Khurasan, Iran. Qayen was formerly the chief town of the same region, which was then called Qainat. The whole area consists of a complicated system of hill ranges (reaching more than 9,000 ft. [2,750 m.]) running northwest to southeast and sinking in the south to the Seistan Basin. The rainfall is greater than in most neighbouring areas, and the population depends largely on *deimi* (i.e., non-irrigated) crops. The principal products are grain, saffron, vegetables, and wool; the *asafetida* plant also grows profusely. Formerly great numbers of camels were reared.

The town of Qayen lies in a broad valley about 200 mi. (320 km.) S of Meshed on the main road to Zahedan. Pop. (1956) 4,414. It is surrounded by a mud wall, which is in a state of disrepair, and the houses of the wealthier inhabitants are outside it. The cultivation of saffron is a speciality of the immediate neighbourhood which supplies nearly the whole of Iran with this commodity. The chief industries are the making of felts and carpets, but the best Qaini carpets are made at Dorokhsh, about 52 mi. SE. The ruins of a fort also lie southeast on the summit of two hills.

Qayen is undoubtedly a place of great antiquity and chequered history. The present town was founded by the Timurid Shahrukh (1405–47) to replace an older town which he is said to have destroyed. Later the Uzbeks took possession of Qayen and held it until Shah Abbas I (1587–1629) expelled them. In the 18th century it fell under the sway of the Afghans and was a dependency of Herat until 1851. See also KHURASAN. (H. Bo.)

QENA: see QINA.

QESHM (QISHM), sometimes styled by the Arabs Jazirat-at-Tawila (Long Island), is the largest island in the Persian Gulf and belongs to Iran. It lies parallel to the Iranian coast between Lengeh and Bandar Abbas and is separated from the mainland by a channel known to mariners as Clarence Strait (Khuran). It is 68 mi. (109 km.) long and has a very irregular outline, with an average breadth of about 10 mi. although it exceeds 20 mi. abreast of Jazireh-ye Hengam (Henjam Island). The coast is generally rocky but the southeastern and western shores have sandy bays and the northwestern is fringed by mud flats. Irregular table-topped hills almost cover Qeshm; several are more than 900 ft. high and one, Kish Kuh, 18 mi. from Basa'idu (Basidu), the westernmost point, and nearly in the middle of the island, reaches 1,331 ft. The geological formation resembles that of the adjacent coast; upper strata of coarse sandstone grit and conglomerate supported by blue Lias marl interrupted by salt plugs. Salt is mined on the southeastern coast and there are naphtha springs. The island is mostly barren but water from wells is fairly plentiful. Cereals, vegetables, melons, and dates are grown near the villages in the north and around the coasts. The main occupations of the inhabitants are fishing and boatbuilding with some camel breeding, stock raising, and weaving. Wild goats, partridges, and rock pigeons are found in the hills, and some gazelles in the plains. The population in 1956 was about 15,000; more than 5,700 live in Qeshm town on the easternmost extremity of the island. They are mainly of Arab origin and are administered by a sheikh of the

Bani Ma'in tribe on behalf of the Iranian government. Qeshm town and Basa'idu were British naval stations early in the 19th century but were abandoned because of the summer heat and malaria. (K. C. B.; H. Bo.)

Q FEVER (also known as **BALKAN GRIPPE**; Ger. **QUEENSLAND FIEBER** or **Q FIEBER**; Fr. **FIÈVRE Q** or **MALADIE DE DERRICK-BURNET**; Ital. **FEBBRE Q**) is an acute, self-limited, systemic disease caused by *Rickettsia burneti* (*Coxiella burneti*), a microorganism of the family Rickettsiaceae. The rickettsiae approximate the smaller bacteria in size and appearance but are obligate intracellular parasites, as are the viruses. Biologically, the rickettsiae occupy a position between the bacteria and the viruses.

History.—Q fever was first recognized as a new disease in 1935 in Queensland, Austr., by E. H. Derrick. According to him, Q stands for "query," an appellation applied because of the many unanswered questions posed by the new disease at the time of its first description. The term "Queensland fever" is therefore unjustified historically (or geographically). The causal organism was originally designated *Rickettsia burneti* by Derrick, after F. M. Burnet, who isolated it. It is frequently referred to also as *Coxiella burneti*, after H. R. Cox, who found that Montana ticks were infected by a rickettsia later shown to be indistinguishable from that recovered in Australia, and who uncovered evidence of the possible existence of Q fever in the United States.

The disease, originally encountered almost entirely among abattoir workers, cattle ranchers and dairy farmers in Australia, and more recently among sheep ranchers, was thought for many years to be restricted to that continent. However, several outbreaks of pneumonitis, later shown to be outbreaks of Q fever, occurred among Axis and Allied troops in the eastern Mediterranean during the winter of 1944-45. These were the first naturally occurring outbreaks of Q fever recognized outside Australia; the disease thereafter was reported from various parts of the world.

Transmission.—While many species of ticks in various parts of the world have been found to be naturally infected, the role of this arthropod in the dissemination and maintenance of the rickettsiae is unclear. It seems likely that some small mammal, perhaps a rodent, serves as a reservoir of the rickettsiae and that ticks keep the infection alive in nature by spreading the rickettsiae from animal to animal within the host species. Man and his domestic livestock (viz., cows, goats and sheep) are not necessary to survival of the rickettsiae in nature and are infected only accidentally.

Tick-transmitted Q fever appears to be rare in man and, in some parts of the world at least, in domestic livestock as well. Since the rickettsiae are excreted in the milk of dairy cows and goats, ingestion of infected dairy products may play a role in the infection of man and livestock. Inhalation of infected material, however, appears to constitute the common mode of infection. The infected animal sheds the rickettsiae through the milk, excreta and, most importantly, through the placenta and the birth fluids. Contamination of the environment leads to air-borne dissemination of the rickettsiae and subsequently to infection of persons in close contact with livestock, contaminated clothing, etc.

Symptoms, Treatment and Prevention.—The incubation period of the disease is from two to four weeks, averaging about 18 to 21 days. The onset of the illness may be gradual but generally is sudden, and the disease is ushered in by fever, chills or chilly sensations, headache, muscle aches, loss of appetite, disorientation and profuse sweating. Symptoms referable to the upper respiratory tract may be present but generally are infrequent and minimal, and pneumonia, even when relatively extensive, may be detectable only by X-ray examination. Although Q fever is, on the whole, a mild disease, it can sometimes result in a severe and protracted illness. The outlook for recovery is excellent; the mortality rate is believed to be less than 1%. The disease is amenable to therapy with wide-spectrum antibiotics, which are highly effective.

Since Q fever appears to be, in large part, an infection associated with occupation, vaccines prepared from killed *R. burneti* can be used to protect those persons exposed to infection. Milk, whether used for table purposes or for manufacture of dairy products, should be pasteurized. See also **RICKETTSIAE**. (E. H. LEN.)

QIFT (Arabic **KUFT**, ancient **COPTOS**, **KOPTOS**), a small village in the United Arab Republic (Egypt) on the east bank of the Nile, 25 mi. N of Luxor, known to the ancient Egyptians as **Qebti**. The town was an early dynastic foundation, the predynastic settlements having been at **Ombos** (ancient **Nubyt**) on the west bank of the river which the early routes followed. **Qebti** owed its importance to the gold and porphyry mines in the district; inscriptions there show that they were being worked in the 1st and 2nd dynasties. Just outside **Qift** **Flinders Petrie** excavated a temple dedicated to **Min** of the Desert Routes and containing three important archaic statues of the god. The town was also associated with **Isis**, who was said to have found **Osiris'** body there. By Old Kingdom times **Qebti** was a place of some importance; both **Pepi I** and **II** built and restored temples there, and it was the starting point of expeditions for **Punt**. By the time of **Thutmose III** the importance of the city had declined, but it revived in the Ptolemaic period through trade with the East. **Queen Arsinoe** was banished to **Qebti** by **Ptolemy Philadelphus**, and held her court there for some years. A rebellion directed against **Diocletian's** taxation on the transit trade led to the destruction of the city in A.D. 292, but later it became the centre of a thriving Christian community and the Coptic Christians of Egypt derived their name from the town. It retained its influence during the Middle Ages, until replaced as the caravan trade terminal by **Kus (Qus)**. Largely as a result of **Petrie's** work there, **Qift** has supplied skilled workers for excavations in Egypt and neighbouring countries. (M. V. S.-W.)

QINA (QENA), a town of Upper Egypt (United Arab Republic) 380 mi. (612 km.) SSE of Cairo by rail and capital of a *muhafaza* (governorate) of the same name. Pop. (1962 est.) 61,000. **Qina** is built beside a canal 1 mi. E of the Nile at its great bend, about 30 mi. N of Luxor. It was called by the Greeks **Caene (New Town)** to distinguish it from **Coptos (Qift, Quft)**, 14 mi. S, whose trade it eventually acquired. This early commerce with Arabia and India, sustained by good caravan routes to the Red Sea, was later reduced to trade with Arabia in dates and grain. **Qina's** importance revived with World War II as a result of its strategic location at the end of a road through the mountains to **Al Qusayr** on the coast. A metre-gauge railway to the small port of **Safajah** was constructed in 1942 but was later abandoned. **Qina** is noted for the manufacture of the porous water vessels, made from local **Pliocene** clays, used throughout Egypt.

QINA muhafaza extends about 3-4 mi. each side of the Nile between the Eastern and Western deserts. Essentially it comprises the great bend in the Nile valley. Pop. (1960) 1,351,358. Area 699 sq.mi. (1,811 sq.km.). The Nile bend and the valley to the borders of **Aswan muhafaza** 50 mi. S are the sites of some of Egypt's most famous antiquities, the most celebrated being the ruins at **Thebes (q.v.)** and the Valley of the Kings which parallels the Nile behind the **Dayr al Bahri** ridge west of the river. Although its soil is fertile, **Qina** is one of the poorest of Egypt's *muhafazat*, principally because the high density of population (exceeding 1,900 per sq.mi.) is coupled with the fact that much agricultural land is still under basin irrigation and therefore yields but one crop a year. About 70% of the occupied population are engaged in agriculture. The principal crops are sugar (60% of Egypt's production), barley, wheat, and millet. **Fenugrecks**, onions, and melons are also grown. Perennial irrigation water, mainly from the **Kelabiya** and **Asfun** canals, is supplied from the **Isna** barrage. Just below **Naj' Hammadi** an important Nile barrage was completed in 1930. This ponds back the Nile to feed the two canals supplying **Jirja muhafaza**. Mineral wealth is limited to stone quarrying and working of sodium nitrate near **Isna**. There are sugar mills at **Armant** and **Naj' Hammadi**. The principal towns are **Qina**, **Luxor**, and **Isna**. (A. B. M.)

QOM (QUM), a city and *shahrestan* (district) in the Central *ostan* (province) of Iran. The town lies on both banks of the **Rud-e Qom**, 78 mi. (125 km.) S of **Teheran**, and at the edge of the great salt desert, the **Dasht-e Kavir**. Pop. (1964 est.) 131,777. The district is irrigated by the **Rud-e Qom** and **Qareh Su** and produces grain, fruits, and cotton of a very long staple.

The town is a stronghold of the **Shi'ah** faith and contains the golden-domed shrine of **Fatima**, sister of the imam **Riza**, which

is annually visited by many thousands of pilgrims. Besides Fatima, at least 10 kings and about 400 saints are interred in Qom and its neighbourhood. Shah Abbas II, whose piety won him high favour with the religious authorities, is buried in a special mausoleum richly adorned with a set of 14 remarkably fine silk rugs, dated 1666. On the south side of the city is a group of five superb mausoleums, mostly of the 14th century, all distinguished by remarkable polychrome stucco ornaments.

Qom has developed into a lively industrial centre, mainly for textiles; glass, pottery, and shoemaking are traditional industries. In 1956 and 1959 the National Iranian Oil Company discovered oil in the Alborz (Elburz) area to the northeast and in the Sarajeh area to the southeast. In the 1960s several dams were completed or were under construction on the upper reaches of the Rudeh Qom.

The city is an important communications centre where the main highway from Teheran splits into three directions: to Isfahan and Shiraz; to Kashan, Yazd, and Kerman; and southwest via Arak to Iraq. It is on the Trans-Iranian Railway with a branch line to Kashan.

(H. Bo.)

QUACKERY, the characteristic practice of quacks or charlatans, who pretend to knowledge and skill that they do not possess, particularly in medicine. The quack makes exaggerated claims as to his power to heal disease, generally for financial gain. The conditions usually treated by quacks are those for which specific methods of treatment, or "cures," have not yet been developed; those particularly feared, such as cancer, venereal diseases and, in the past, tuberculosis; those with frequent remissions and recurrences, such as arthritis, neuritis and migraine; and mental disturbances. People yield to quackery in times of great stress, pain or sorrow. In the absence of exact knowledge, and sometimes even in its presence in the face of insurmountable difficulties, the credulous person craves a miracle. He is ready to be overwhelmed by the personality and the claims of the charlatan.

The typical quack may be a man or a woman, but is likely to be striking in appearance and personality. In the past crippled persons, such as hunchbacks; rulers, such as high priests and kings; mystics and mentally disturbed persons were believed to possess special powers in healing disease. The modern charlatan in his announcements features an alphabetical appendage, indicating the possession of academic degrees that, however, were not conferred by any recognized scientific organization or university. The charlatan originally may be self-deluded as to his powers, but sooner or later he becomes aware of his failures. He then continues in his practice, consciously deluding those who depend upon him. He is aided by the reluctance of persons who have consulted him with disadvantage to acknowledge the fact, and by magnification of his apparent successes. Advances in psychosomatic medicine have helped to explain some of the healings recorded by quacks.

Techniques.—Whenever a new discovery is made in any field of science, the charlatan may take advantage of public interest and lack of information to utilize it with exaggerated claims. Lack of general knowledge encourages occultism, and the characteristic claim of the quack is the possession of a formula, method, device or product unknown to other physicians or scientists. At the time of the American Revolution, for example, a quack named Elisha Perkins (1741–99), aware of public interest in the recently discovered electricity, invented "metallic tractors" to draw disease out of the body. These were two rods of brass and iron, about three inches long, one of copper, zinc and gold, the other of iron with some other metals; they cost 1s. to manufacture and sold for \$5. James Graham (1745–94) in England set up a temple of healing in which he burlesqued the principle of electricity, promising cures and rejuvenation.

Knowledge of powerful drug substances derived from plants (digitalis, belladonna, cascara sagrada, quinine and castor oil) or from metals (mercury, arsenic and particularly gold) led to the development of nostrums that were exploited with false, misleading or exaggerated claims to cure such diseases as tuberculosis, syphilis, cancer, kidney diseases and gynecological, digestive and rheumatic disorders. Sometimes the quack or purveyor of nostrums did not trouble to include a potent drug but merely used

any bitter-tasting, dark herb or vegetable with common salt or sulfur. Toward the end of the 19th century alcohol was used as a solvent, and it yielded its typical effects to the satisfaction of the users. Many modern nostrums depend principally on aspirin.

With the discovery of radium, claims were made for mixtures said to contain this substance. In a few instances some radium actually was included, and users died years later from the effects of radium on the bones. Radium was said to be incorporated in magical magnetic belts, and radium plasters with infinitesimal amounts of radioactivity were purveyed.

Increasing knowledge of the glands of internal secretion gave rise to preparations for rejuvenation, beautification and sexual power. Vitamins have been incorporated in preparations for growing hair or preventing grayness, without any real evidence that they could be helpful. Indeed, in the realm of cosmetology, quackery and nostrums seem destined forever to reap a pecuniary harvest.

Because people believe in "nature," uncooked foods, systems of exercise, recital of ritualistic codes, manipulation of bones, muscles and tendons, complicated machines of no particular merit, heat, cold, baths, lights (plain and coloured), static electric currents and even radioactivity have been vaunted as useful in the control of disease and the promotion of health.

With the development of techniques for advertising and promotion, the quacks thrived until legislative controls were brought into action. As early as 1843 a leader in advertising said that pain or the fear of pain attracted the greatest interest in mankind, and that for this reason medical advertising took most of the space available in the press. Vanity had the next strongest appeal. Education of the public in physiology, anatomy and hygiene have not served to dispel gullibility. Quack advertising still relies on blatant exaggeration, use of unusual terms (such as "dyskinesia" for constipation), creation of fear, promise of secrecy and financial saving (actually the employment of nostrums and quackery invariably results in greatly increased and prolonged expense). With the coming of radio, some quacks secured radio stations to sell promised cures, and even television has been so employed.

Legislation.—In the United States, quackery varies from state to state according to the limits permitted by law. In some states it is limited almost entirely to the sale of drugs and herb preparations. In other states institutes or sanatoriums are conducted by quack doctors.

In Great Britain a violator is held liable if he holds himself out as a "listed" or recognized medical practitioner or if a death occurs associated with his ministrations; there the law considers that a person consults a quack at his own risk. The continental European countries have not been successful in curbing quackery. In Germany during World War II the unlicensed healers were actually encouraged and formed an association which received governmental recognition. In Latin America quackery is rampant.

In the United States the Food and Drug act of 1906 eliminated the widely advertised quack cures for cancer, tuberculosis and other serious diseases; thereafter the same preparations were sold as cures for coughs, colds, pains and aches and minor complaints. Labels were required to carry information as to content of certain ingredients, warning as to hazards and, in some instances, references to diseases that would not be helped by the preparation. The Federal Food, Drug and Cosmetic act of 1938 and the Wheeler-Lea act (also 1938) provided a certain amount of governmental control over claims made in advertising, in newspapers and magazines, over radio and television, in circulars and on labels. Such controls are exercised, however, only on the products in interstate commerce. Individual states vary in the amount and kind of control they exert. In 1962 the Food, Drug and Cosmetic act was amended to require proof of effectiveness of all drugs introduced for sale, retroactive to 1938, and giving the U.S. Food and Drug administration control over drug advertising. Finally, the post office department has authority to forbid the use of the mails when convinced that they are being used fraudulently. Organizations concerned with such conditions as cancer and heart disease conduct continuous campaigns of public education,

warning against the depredations of medical quackery and the sellers of nostrums, and the United States public health service also has undertaken such activities. The state medical licensing boards, medical societies and Better Business bureaus also are concerned with the protection of the public in these fields.

For these reasons quackery has steadily diminished, and the depredations of quacks have been severely limited. Nevertheless the nature of the human mind is such that charlatans will no doubt continue to appear and wreak damage from time to time until society with a social conscience and legal controls catches up with them. See also FRAUD.

See Morris Fishbein, *Fads and Quackery in Healing* (1932); Grete de Francesco, *The Power of the Charlatan* (1939). (M. Fl.)

QUACK GRASS (*Agropyron repens*), a perennial grass of the barley tribe (Hordeae), called also couch grass or quitch grass. It is native to Europe, common in northern Europe and widely naturalized in North America. Quack grass has bright-green, smooth, stiffly erect stems, one to four feet high; leaves with flat or inrolled blades; and terminal flowering spikes, two to six inches long, composed of numerous, usually five-flowered spikelets, which often bear short awns. Sometimes it is grown for forage, but it is better known as a troublesome weed in cultivated fields, especially on rich soil, spreading rapidly by its creeping rootstocks, which are ivory coloured and sharp pointed. The best method to eradicate it is to root it out.

QUADRATURE (Lat. *quadratura*, a making square), in astronomy, that aspect of a heavenly body in which it makes a right angle with the direction of the sun. The moon at first or last quarter is said to be at east or west quadrature, respectively.

A superior planet (outside the earth's orbit) is at west quadrature when its position is 90° W. of the sun (see drawing). It rises around midnight, reaches the south meridian near sunrise and sets near noon. At east quadrature the planet is near the meridian at sunset and sets near midnight. At both quadratures, the planet is at gibbous phase, but only in the case of Mars does it show up conspicuously gibbous.

In mathematics, quadrature is the determination of a square equal to the area of a curve or other figure. Integration by quadratures means calculation by a step-by-step process when no analytical expression for the integral is available. (H. M. Lo.)

QUADRILATERAL, in geometry, a figure formed by four straight lines. It is said to be plane or skew according to whether the four lines do or do not lie in one plane.

Let us consider the plane figure bounded by four lines terminated at the vertices. A line joining a pair of opposite vertices is called a diagonal. The area of such a quadrilateral is half the product of the length of one diagonal by the sum of the perpendiculars drawn to this diagonal from the other two angular points. The sum of the squares of the four sides of such a quadrilateral is equal to the sum of the squares of its diagonals increased by four times the square of the line joining the midpoints of the diagonals. If the vertices of such a quadrilateral lie on a circle, the product of the diagonals is equal to the sum of the products of the opposite sides. It is in projective geometry that the quadrilateral plays its most interesting role. If A, B, C, D are four points in a plane no three of which are collinear, then the lines AB, BC, CD, DA, each taken to be of indefinite extent, form a quadrilateral (see figure). These sides intersect in pairs not only in the four given points (called vertices) but also in a point E on both AB and CD, and in a point F on both BC and AD. The points E and F are also called vertices. Then each side of the quadrilateral contains three vertices. Two vertices

QUADRATURE OF A SUPERIOR PLANET

QUADRILATERAL ABCD. ALL LETTERED POINTS ARE VERTICES

not on the same side are called opposite. A line joining two opposite vertices is called a diagonal. The configuration so described is called a complete quadrilateral. The dual figure is called a complete quadrangle. These figures are of fundamental importance in projective geometry (q.v.).

QUADRILLE, a lively dance, executed by four couples arranged in a square. A form of *contredanse* known by 1710, the quadrille crystallized about 1815 in the general form popular since then, and consisting of five figures: *le pantalon*, *l'été*, *la poule*, *la pastourelle* or *la tréneise*, and the *finale*. The music was often based on operatic melodies; dance patterns were subject to great variation. Although steps and figures have undergone considerable modification, quadrilles such as the lancers are still among the most popular square dances. In theatrical terminology, quadrille has denoted: (1) small groups of dancers in 18th-century ballet; (2) Paris night-club dancers of the 1890s, immortalized by Henri de Toulouse-Lautrec; (3) divisions of ensemble dancers at the Paris opera in the 20th century. (L.N. ME.)

QUAESTOR (derived from Latin *quaerere*, "to investigate"), a magistrate usually concerned with finance, in ancient Rome. Tacitus attributed the origin of the quaestorship in Rome to the regal period, but all other evidence refers to the republic. The two *quaestores paritidii*, who were appointed by the consuls and were concerned with capital offenses, are mentioned in the Twelve Tables. The financial quaestors may have arisen from these as assistants of the consuls, but more probably arose independently with the development of a public treasury, and were like the financial officials called *mastroi* in certain Dorian cities of the West. From 447 onward they were elected for annual terms in the *comitia tributa* (see COMITIA), with the consul presiding. In 421 the number was raised to four to provide military assistants to the consuls, and opened to plebeians, and after the conquest of Italy was probably raised to eight. L. Cornelius Sulla (dictator 81-79) made it 20 and Julius Caesar 40, but Augustus reduced it to 20, the usual number under the empire. The connection of quaestor with consul, and later with the higher magistrate he assisted, was considered analogous to that between father and son. The office was held after the term of military service, and after Sulla the minimum age was 30, which was reduced to 25 under Augustus. The year of office began on Dec. 5. After Sulla it gave automatic entrance to the Senate, and under the empire remained the first qualifying office in a senatorial career. For insignia the quaestors had a chair (*sella*), and had the fasces (q.v.) when they held command in provinces as *quaestores pro praetore*.

Their duties were varied. The two urban quaestors were responsible for the security of the funds, coin and bullion, in the public treasury and for the accounts, as well as for the laws, decrees, and military standards deposited there. They could levy sums owing to the treasury and conduct sales for it. Augustus placed praetors in charge of the treasury, but from A.D. 44 to 56 it returned to quaestors especially selected for three-year terms. The consuls and each of the provincial commanders had a quaestor (the governor of Sicily had two) especially, but not exclusively, concerned with his financial arrangements. The quaestor exercised a delegated jurisdiction, could command troops, and was sometimes left in command when his superior returned. Assignments to provinces were by lot, but a commander's wish might be considered, and the term could be prorogued. Quaestors continued to serve under the empire under proconsuls in senatorial provinces.

In Italy under the republic quaestors collected funds and levied men for the fleet; one, like Saturninus in 104, had the onerous charge of the grain supply at Ostia; one was stationed (still under Tiberius by ancient custom) at Cales in Campania with much of southern Italy in his province; one had the care of water supply in Rome; and one was in Gaul. During the empire their duties passed to imperial appointees, the ones in Gaul and Ostia being given up under Claudius, while special quaestors of the emperor appeared who performed such duties as accompanying him and reading his letters to the Senate. Under Claudius the financial burden of paving roads was changed to the giving of gladiatorial games. The office continued into the 3rd century as a rank and survived into the late empire.

The *quaestor intra Palatium* of the late empire, newly created under Constantine, replaced the praetorian prefect in the internal administration. He headed the *consistorium* (the imperial council), drew up laws and answers to petitions, and was responsible for the list of minor staff officers (*laterculum minus*).

The quaestor in Oscan towns was probably derived from Rome. Quaestors were regularly minor magistrates in colonies and *municipia* with duties similar to those in Rome. Private associations often called their financial officers quaestors.

QUAGGA, a zebra-like animal (*Equus quagga*) formerly found in vast herds on the great plains of South Africa but now extinct, apparently the last having died in 1872 in the London Zoo. The colour of the head, neck, and upper parts of the body was reddish brown, irregularly banded, and marked with dark-brown stripes, stronger on the head and neck, and gradually becoming fainter until lost behind the shoulder. There was a broad, dark, median dorsal stripe. The undersurface of the body, the legs, and tail were nearly white, without stripes. The crest was high, surmounted by a standing mane, banded brown and white. See ZEBRA.

QUAHOG, also spelled **QUAHOG** or **QUAHOG**, is a corruption of the word *paquahock* used by the New England Indians for the hard-shell clam *Mercenaria mercenaria* in the family Veneridae. The name quahog is used only on the Atlantic seaboard of the United States and particularly in New England. The shell of this clam is large, thick, and solid, marked with concentric growth lines and ridges. It is a dirty gray in colour outside; inside it is often marked with purple, and it was from this that the Indians made their purple wampum. The quahog has short siphons and so does not burrow deeply into the sand; often a portion of the valves is protruding, or the shell may lie on the surface. It ranges from the intertidal zone out to depths of several fathoms and is found on sandy, muddy bottoms. This clam was an important item of food to the Indians and the early settlers and continues to support an important industry on the Atlantic coast from Nova Scotia to Maryland. The young clams, known as cherrystones, are eaten raw; the larger ones are cooked in a variety of ways, though chowder is perhaps the commonest. The black, mahogany, or ocean quahog, *Arctica islandica*, has a heavy dark covering on the outside of the shell. This edible species lives in deeper water and is dredged in quantity off the New England coast. Young of both species are important food for bottom feeding fishes. *Mercenaria campechiensis*, the southern quahog, is also fished commercially. See also CLAM. (R. D. T.)

QUAIL, a game and table bird known throughout Europe, Asia, and Africa. The common quail (*Coturnix coturnix*) varies in colour, but in general is reddish brown above marked with dark brown and buff below, passing into white on the belly. Essentially migratory, the quail nests on the ground, laying 9 to 15 yellowish eggs spotted with dark brown. Immense numbers are netted during the autumn migration in Mediterranean countries. It has been said that the "manna" that came down from the heavens to the Israelites during their wanderings in the desert may have been, in part, a large migration of quail.

Quails are protectively coloured, and are particularly difficult to see when they "freeze"; they tend to remain motionless until pressed closely, then take to sudden, low, erratic flight. Family groups are in the habit of sitting in circles, facing outward. They thus keep warm and at the same time maintain a watch for danger. When approached, the circle of birds "explodes" in all directions, tending to confuse the predator.

The quail is now rare in Great Britain. It feeds largely on weed seeds and insects and is decidedly a beneficial species. Related forms include the rain quail (*C. coromandelica*) of India, the African quail (*C. delegorguei*), and the Australian stubble quail (*C. pectoralis*). The North American quails belong to a

QUAIL (*COTURNIX COTURNIX*)

different subfamily of the Phasianidae. They include the bobwhite (*q.v.*; *Colinus virginianus*), of which some 20 races occur from Mexico and the West Indies to Canada, the California quail (*Lophortyx californicus*), the scaled quail (*Callipepla squamata*), Gambel's quail (*Lophortyx gambelii*), mountain quail (*Oreortyx pictus*), and the harlequin quail (*Cyrtonyx montezumae*). The button quails (*Turnix*), lacking the hind toe in most species, are now regarded as related to the cranes. *Turnix sylvatica* ranges from Spain to the East Indies, with various races.

(K. P. S.; Hr. Fr.)

QUAKERS, the name by which members of the Religious Society of Friends (Friends Church) are frequently known. George Fox, founder of the society, records that in 1650 "Justice Bennet of Derby first called us Quakers because we bid them tremble at the word of God." It is likely that the name, originally derisive, was also used because many early Friends, like other religious enthusiasts, themselves trembled in their religious meetings and showed other physical manifestations of religious emotion. The term was in fact probably used of other enthusiasts, as in a 1647 reference to "a sect of women (they are at Southwark) come from beyond sea, called Quakers" or a 1646 reference in the parish register of Milford, Hampshire, each predating Friends in the respective localities by more than six years. Despite early derisive use, Friends used the term of themselves in phrases such as "the people of God in scorn called Quakers." No embarrassment is caused by using the term to or of Friends today. See FRIENDS, SOCIETY OF. (E. H. M.)

QUALITIES. The word "quality" has, both in philosophy and in ordinary speech, a long history. It appeared in English as a translation of the Latin *qualitas*, a word coined by Cicero to translate the Greek *poietes*; and this Greek word had itself been coined by Plato (*Theaetetus*, 182a), with apology for its barbarous character, and employed as a technical term by Aristotle in his doctrine of categories (see CATEGORY). In spite of this highly artificial beginning, the word "quality" soon became acclimatized in ordinary English; in philosophy, however, its uses have been various and somewhat obscure.

The ordinary uses of the word (which cannot here be exhaustively dealt with) may be broadly distinguished under two headings. First, the word is sometimes employed as a synonym of "property" or "characteristic": in this sense it would cover almost anything that might be ascribed to an object for the purpose of describing it—its colour, shape, dimensions and so on. In the same sense honesty, prudence, obstinacy, etc., may be spoken of as "qualities of character." Second, the word is used, perhaps more commonly, in contexts where merit, grade or value is in question. Where, for example, two kinds of cloth are said to dif-

fer "in quality," it would usually be meant not merely that they differ but that one kind is better (by the appropriate standards) than the other; it might indeed be said to be of better, or higher, quality. Similarly, when Emerson wrote that "there is more difference in the quality of our pleasures than in the amount," he undoubtedly meant to convey that some of our pleasures are better, more valuable, and not merely more intense or more prolonged than others. It is usually in this way that the word "quality" is to be understood when a contrast is stated or implied with "quantity." The word is also often employed by itself in the sense of "good quality," as in the old phrase "persons of quality" or in such advertisers' phrases as "quality groceries." In view of the existence and, perhaps, prevalence of this second use, it is important to remember that (in the first sense) a "quality of character," for example, is not necessarily good or desirable. Cowardice is as truly a quality of character as bravery.

Qualities and Relations.—The traditional distinction between qualities and relations, so common that it can hardly be regarded as technical or philosophical, has sometimes been attacked as being philosophically unimportant. It cannot be denied, however, that there is such a distinction, or that it is sometimes convenient to employ it. What the distinction is can be roughly indicated by examples. Colour would be said to be a quality, since, in saying of what colour an object is, nothing need be mentioned other than that object to which the colour is ascribed. Proximity, on the other hand, would be said to be a relation, since, in employing the phrase "is close to," two objects must be mentioned, one of which is said to be close to the other. Similarly, a statement of the form "*Y* is between *X* and *Z*" might (rather artificially) be said to assert the relation of intermediacy—a "three-term" relation, since mention must be made in the statement of three things, one being said to be between the other two. A connected and sometimes convenient notion is that of "relational quality." For example, it might be said that being tall is a relational quality since, though it is clearly not a relation (the sentence "Jones is tall" is complete in itself), it could be held that in calling someone tall a comparison is implied between his height and (roughly) that of most other men.

Qualities and Predicates.—The foregoing brief distinction between qualities and relations might suggest the view that, in all subject-predicate (as distinct from relational) statements, the predicate is employed to ascribe a quality to that which the subject-expression is used to designate. It would be usual, however, and seems desirable, not to accept such a general principle without qualification; for there are many expressions, properly used as predicates and not obviously complex, which are yet used so differently from others that it seems inadvisable to regard them all as alike in standing for qualities. It would, for example, be reasonable to deny that the word "real" stands for a quality. For whereas the word "yellow," for instance, is ordinarily (literally) employed in just one way, namely in ascribing a particular colour, and so might be said always to stand for the same quality, the force of the word "real" varies greatly from context to context. It would be most unnatural to insist that a real (as opposed to a pantomime) horse and a real (as opposed to an illusory) advance share a single quality, reality; the word "real" takes its particular force in each context from the implied contrast, and in this respect, if in no others, the cases differ completely.

Nonnatural Qualities.—An instance which has aroused more controversy, though it is not perhaps of greater importance, is that of the predicate "good." G. E. Moore, in his influential *Principia Ethica* (Cambridge, 1903), launched an attack on what he called the naturalistic fallacy. He distinguished in the course of his argument between the "natural qualities" of objects—for example their colour, shape, texture or weight—and "nonnatural qualities," of which his primary instance was goodness; and the naturalistic fallacy, he claimed, was committed by anyone who sought to define a nonnatural quality in terms of a natural quality or qualities. Doubts were soon expressed, both by Moore himself and by others, about the meaning to be attached to his expressions "natural" and "nonnatural." But other critics were inclined to question whether goodness was a quality at all, of any variety; and some insisted

that it was not. (Cf. the symposium "Is Goodness a Quality?" in the Aristotelian society's *Supplementary Volume XI*, London, 1932.)

Now this denial might seem surprising in the light of the ordinary use of the word "quality." For one of its most common uses, as remarked above, is in contexts where merit, goodness or badness, is at issue: good apples are of better quality than bad ones. Moreover, it seems entirely natural to say that goodness of heart is an admirable quality of character. If so, it would seem that there could be no objection to the assertion that goodness is a quality.

The philosophical objections to this assertion are somewhat complex but may be summarized as follows. It has been urged that to classify goodness as a quality reveals, or at least invites, misunderstanding of the distinctive character of value judgments. To say that anything *Q* is a quality, it is said, is to imply that a statement of the form "*X* is (or possesses) *Q*" gives a description of *X*, or states a fact about *X*; and it has commonly been held that descriptions or statements of fact, properly so called, must be sharply distinguished from judgments of value (or, that describing an object must be distinguished from expressing commendation or condemnation of it). Hence, Moore's distinction between "yellow" as standing for a natural quality and "good" as standing for a nonnatural quality was held to be inadequate; for it implied that judgments of value were no more than a special kind of statements of fact, or statements of a special kind of facts, thus obscuring the supposedly more fundamental distinction between statements of fact, of whatever sort, and judgments of value. Moore's argument was also held to raise needless apparent problems about the ways in which judgments of value could be supported or attacked, disputed or justified; for it appeared that nothing clear and satisfactory had been said, or could be said, about the way in which the presence or absence of nonnatural qualities could be detected.

However, this criticism of Moore is inconclusive. For it is not in fact the case, as has often been assumed, that descriptions or statements of fact must be evaluatively neutral. It is proper to say that a man may be *described* as dishonest, though thereby his character is condemned; it may be a *fact* that he is dishonest and hence a statement of fact to say so. But if so, to say that goodness is a quality and to concede that the assertion "*X* is good" may be a statement of fact or a description does not oblige one to misrepresent the peculiar character of value judgments. One may say that, in stating the fact that *X* is good or in describing *X* as good, one is necessarily also commending *X*—that goodness is precisely the quality which commendable things are said to possess. Those philosophers who have distinguished so sharply between "descriptive" and "evaluative" terms might well be held themselves to have misstated the same distinction which Moore was accused of misstating, in his distinction between natural and nonnatural qualities.

A better reason for denying that goodness is a quality might be found in the extreme generality of the word "good" (cf. Aristotle, *Nicomachean Ethics*, I, v). It would be unpalatable to maintain that the word is actually ambiguous; but if it is not ambiguous and if it stands for a quality, one must hold that, whatever things are called good, the same quality is thereby ascribed to them. But this in its turn seems most unnatural. Can good arguments, good apples, good deeds and good cricketers be plausibly said to share one common quality of goodness? If so, should one not expect a sound judge of cricketers to be thereby equipped to judge apples also, or arguments? But this is obviously contrary to facts. It is noteworthy that the "admirable quality of character" mentioned earlier was not in general goodness but in particular "goodness of heart." It seems that some such particularization of goodness is essential if it is to seem natural to speak of it as a quality. Moore, indeed, when he said that goodness was a nonnatural quality, had restricted his discussion to the alleged special use of "good" in moral contexts. But this restriction seemed somewhat arbitrary, nor is it clear how his argument could be extended if the restriction were dropped. It could not well be held that "good" in other contexts stands simply for natural qualities; but if not, it is not clear how Moore could

distinguish between moral and other contexts, nor why he should be at such pains to do so.

Primary and Secondary Qualities.—Locke's celebrated distinction between primary and secondary qualities (*Essay Concerning Human Understanding*, ii, ch. 8), of which some notice must be taken here, in fact exhibits the disconcerting feature that some of those things between which he thus distinguishes would not naturally be regarded as qualities at all. The primary qualities of matter, he says, are "solidity, extension, figure, motion or rest, and number"; the secondary qualities are "colour, sounds, tastes, etc."—the "etc." being evidently designed to cover at least smells and warmth and cold. Of these "motion or rest" would usually be spoken of as states, not qualities—partly at least because an object that was at rest, being set in motion, would not be said itself to undergo alteration, as would be implied by saying that it had lost one quality and acquired another. Number also is not commonly thought of as a quality: yellow flowers are all individually yellow, but ten flowers are not all individually ten. To this it might be replied that the quality of being ten belongs not certainly to the members of a collection of ten things but simply to the collection itself. There are further objections to this reply (cf. G. Frege, *Foundations of Arithmetic*, Eng. trans. by J. L. Austin, Oxford and New York, 1950, p. 396 ff.); but here it will be sufficient to appeal to the obvious difference between the question "Of what sort? (*qualis?*)" and the question "How many?" as a sufficient reason for refusing to classify number as a quality. From the list of secondary qualities, sounds at least seem to be similarly misclassified. It is clear enough that an actual sound is not a quality of that which makes it, though the capacity, tendency or disposition to make that sort of sound or to be concerned in the making of it might well be so regarded.

Apart from these perhaps minor points, Locke's own account of his important distinction is regrettably confused. He says that our ideas of primary qualities "resemble" those qualities ("their patterns do really exist in the bodies themselves") but that our ideas of secondary qualities are wholly unlike that in objects which causes us to have them. Sometimes, apparently confusing qualities with ideas, he says that secondary qualities, unlike the primary, would not exist at all in the absence of suitably sensitive observers. Sometimes he seems to contend that our ideas of secondary qualities are so various and fluctuating that we cannot say that any such qualities are really "in" objects themselves. He certainly comes very close to saying, and by Berkeley was understood to mean, that our ideas of secondary qualities are only a "false imaginary glare," tempting us to ascribe to objects qualities which really they do not possess at all. It is accordingly necessary to inquire what it was that he was seeking, though unsuccessfully, to convey; and here we must take notice of two different distinctions, with both of which Locke was evidently concerned, though he does not clearly indicate that they are two and different.

First, he was clearly influenced strongly by current scientific accounts of the process of perception. He officially regards the qualities of matter as the causes of our "ideas of sensation" and hence is led to think of matter as really characterized by those qualities required in the current explanatory theory. Now the theory current in Locke's time was a mechanical one, "corpuscles" being supposed to act "by impulse" on the sense organs; it is accordingly not surprising that his list of primary qualities includes all and only those features that are of mechanical importance—solidity, shape, size, motion and number. The secondary qualities, perception of which is accounted for by the action of corpuscles supposed to have primary qualities only, are thus thought of as an almost irrelevant intrusion, making their appearance because and only because the world happens to contain appropriately sensitive organisms.

But, second, Locke also says that primary qualities are those which "the mind finds inseparable from every particle of matter"; and he later suggests that they constitute the "real essence" of matter. Now here his case seems to be founded not on scientific but on logical or conceptual considerations. He seems to say that possession of the primary qualities is, and possession of secondary qualities is not, essential to being "material"—that the concept of

materiality includes the primary qualities but not the secondary. And this view, though baldly stated, seems to be right. It is clear enough that anything that we should regard as a material object must be individually distinguishable from other things (countable); must have some shape and dimensions; must be moving or at rest in space; and must be "solid" (in the sense at least of excluding other things from the volume of space occupied by itself). It is equally clear that a material thing is not logically required to make any sound, or to have any taste or smell. The case of colour is more controversial. For sight is in practice the most important of our senses, and it might be urged that any material object must be at least so far coloured as to be visible, accessible to the important sense of sight.

It appears, however, that visibility is actually less important than this would suggest; there is, for example, no conceptual difficulty in the idea of the Invisible Man. By contrast, an "intangible man" would be thought of not as a genuine though peculiar kind of man but rather as not a man at all—as a ghost, a vision or a hallucination.

Many other questions of intricacy and interest are suggested by Locke's distinction, though not raised by Locke himself—questions, for example, about the importance and limitations of measurement in our dealings with material things and about the relation between actual or conceivable metrical scales and the (usually) rough "qualitative" distinctions marked in everyday speech.

There is also a large family of questions which might be grouped under the heading "appearance and reality." It is, however, impossible to pursue these topics in the present context.

Qualities and Substance.—Something perhaps should be said here of the not wholly obsolete question, whether a material object can be identified with the sum of its qualities, or whether we must (as Locke held) "suppose always something besides" the qualities, in which they inhere or to which they belong—something to which he and others have given the name of substance (*q.v.*). The disagreement on this question appears to be a case of cross-purposes. On the one hand, an object clearly cannot be simply identified with a collection of qualities; for it is an elementary point of logic that qualities must be qualities of something—that there must indeed be something which they qualify. On the other hand, there is no need to reach Locke's conclusion that this is always a "something we know not what," for which "substance" is simply an arbitrary name. For that in which, say, the qualities of a table inhere is of course a table, a something we know quite well. Historically, the controversy on this issue seems to have arisen from a *prima facie* perverse but in fact not unpersuasive tendency to regard the ultimate possessor of qualities as an essentially characterless and hence unperceivable and indescribable stuff; while the justified opposition to this line of thought expressed itself by reaction in the mistaken form of a denial that anything but qualities need be admitted.

To escape from the dilemma it is necessary to see that, while qualities must certainly inhere in or belong to substances (or at any rate things which are not themselves qualities), there is no need to suppose the existence of a single characterless stuff in which all qualities ultimately inhere. A thorough removal of the difficulty could probably be best secured by an examination of the related but contrasting roles of substantival and adjectival expressions, together with some investigation of such pedestrian expressions as "stuff," "matter" and "something."

Quality of Propositions.—A specialized use of "quality" has long been made by logicians in the Aristotelian tradition. Under this heading propositions are classified as either affirmative or negative. The term "quality" is employed in this way in contrast with a technical use of "quantity"—the three quantities of propositions being "universal," "particular" and "singular." Kant attempted to introduce, symmetrically with the three headings of quantity, a third quality which he called "infinity"; but this alleged further distinction was not well founded and did not find favour.

(G. J. Wx.)

QUANTITY THEORY OF MONEY, a theory concerning the relationship that exists between the quantity of money

within an economic system and the purchasing power or value of one unit of money. In its extreme form, the quantity theory states that the price level changes because the quantity of money changes and that the price level moves in the same direction and in the same proportion as the change in the quantity of money. This implies that the total amount of money in an economic system remains constant in value no matter how many units of money there may be.

Equations.—The quantity theory of money may be formulated in one form or another of a quantity equation. Two traditional forms are $MV = PT$ and $N = P(kT)$. The former is the Fisherian equation, named in honour of the U.S. economist Irving Fisher; the latter, the Cambridge equation, developed principally by Alfred Marshall and A. C. Pigou at Cambridge University in England. There are more sophisticated formulations of the quantity theory of money, but these two illustrate the basic concept involved.

M and N in these equations are the supply of money, commonly defined as the sum (expressed in a nation's monetary unit) of coin and paper currency and checking deposits in banks. In both equations P is an average or index of prices for the marketable goods and services that are measured by T . Current usage is to include in T only the goods and services that comprise national product or national income, omitting the stock of existing wealth and all securities. Hence PT is the aggregate market value of goods and services currently produced and exchangeable for money.

V and k are related reciprocally and express the desire of persons and business firms to have money rather than other forms of wealth. The Fisherian equation is relevant to a specific period of time, and its V is the frequency with which the average unit of money is spent during the period. This frequency is low if money users wish to retain a large proportion of their money income for relatively long periods; it is high if they dispose of their money income soon after receiving it. MV represents the spending of money during a period of time and PT is the value of the goods on which it is spent. The Cambridge equation is relevant to a moment of time, and its kT is the real or physical amount of goods which money users do without in order to retain their money.

The derivation statistically of quantity equations is difficult. There is no faultless measurement of the real goods T or of the price level P at which the goods are traded for money. The desire to hold money (represented by k) can be estimated only from the amount of money actually held. Finally, there is disagreement as to whether the money supply M should include all or merely part of coin, currency, and checking deposits, and also whether it should include time and savings deposits in commercial banks and other financial assets.

The theory that price levels vary as a result of, and in proportion to, changes in the supply of money specifies that T and V or k should be stable and should be independent of the supply of money. Otherwise, the effect of, say, an increase of M in inflating P would be either suppressed or magnified by changes in the flow of goods or in the desire of money users to have money rather than the goods and services that money buys.

The theory may be expressed more conservatively, for a context in which T and V or k are independent of the supply of money but variable. Under such circumstances, the theory would hold that prices vary other than proportionally with money—less than proportionally, for example, while T and k rise. Still, with appropriate adjustments for T and k , money is the propellant of change in the price level, and the impact tends to be proportional.

The quantity theory implies a process by which changes in the supply of money can influence the price level. This process is an adjustment of the amount of money demanded by money users to the supply of money. The demand for money may be visualized as $M' = P(kT)$, with desired balances M' responding positively to the other elements of this equation. The supply of money M depends not on money users but on the ability and willingness of the monetary system to provide money. There is equilibrium when $M = M'$. If the equilibrium is disrupted by an increase in M , the excess of money supply over money demanded is spent

on goods, services, and securities. If the flow of goods and services is given, and if both old and new money circulate at the same V , commodity prices P must rise until M' is once more equated with M and the excess supply of money is dissipated by price inflation. In the process of adjusting demand to supply, prices have risen less than in proportion to the increment of money, but when the process is completed and a new equilibrium is established the price inflation is proportional.

Relation to Economic Thought.—The quantity theory that proportional changes in price level adjust the demand for money to the supply has been an integral part of some formal systems of economic reasoning. These bodies of doctrine, sometimes brought to bear on economic problems of the 20th century, purport to explain the behaviour of the entire economic system. They assume that V is stable, or very slow to change, reflecting persistent habits of money users in holding money balances and making money payments. They assume, further, that T is determined by such nonmonetary factors as the labour force, labour productivity, the relationship of wage rates to prices of output, and interest rates. The composition of T and the ratios of individual prices to each other reflect comparative costs of different goods and their comparative utilities to buyers. Everything that is real is determinable independently of the demand for and the supply of money. According to quantity-theory reasoning, money merely determines the absolute level at which price relationships are established. In this view, money is a veil which in equilibrium may obscure, but does not affect, real determinants of economic welfare. Moreover, it should be the goal of monetary policy, working primarily through the supply of money, to keep money in this neutral role.

Neutral money, the argument continues, may be distorted by unsound policies. If monetary expansion exceeds growth in demand for money at a stable price level it must lead to consequences that are socially objectionable. The intermediate consequence is an excessive demand for goods and services that will cause inflation of price levels if the excess supply of money is continually replenished. If monetary expansion ceases, the high level of demand for goods and services collapses, and economic recession follows. The outcome of continuous inflation is maldistribution of income and misallocation of productive resources, even a catastrophic paralysis of the economic and social structure. The outcome of a brief period of inflation, with deflation in its wake, is the business cycle, involving waste of scarce resources.

It is concluded that, in the transitional phases of inflation or of cyclical movement, the quantity theory of money does not apply precisely because V and T are subject to change. According to the neutral-money doctrine, the quantity theory does explain differences in price levels between states of general economic equilibrium. Since the quantity of money affects only price levels and not welfare in equilibrium, and since changes in the quantity of money reduce economic welfare in transitional phases, the optimal policy regarding money is to expand it only as kT grows.

Some extremists have contended that, in the interest of monetary stability, "cheap" or "easy" money should be avoided even in recession. However, the predominant quantity-theory view is that money should be expanded to stop recession if only because recessions themselves usually originate in undue restraint on the money supply. Inappropriate changes in the money supply induce business cycles; appropriate changes in the money supply can ameliorate or even prevent cycles.

Historical Influence.—From its primitive antecedents in the economic literature of Greece and Rome to its modern formulations, the quantity theory of money has been an important strand in the development of economic thought. As developed by John Locke in the 17th century, David Hume in the 18th century, and others, it was a weapon against the Mercantilists, who regarded wealth and money as identical. (See MERCANTILE SYSTEM.) If the accumulation of money by a nation merely raises prices, the mercantilist goal of export surpluses and imports of monetary metals for enhancement of national wealth must be illusory.

In the 19th century the quantity theory contributed to the gains of free-trade doctrine over protectionism. If the intermedi-

ate effect of import duties is to create an export surplus of goods and services, the ultimate effect is that the export surplus stimulates imports of gold, an expansion of the supply of money, and a rise in domestic price levels that nullifies the trade restriction. The duties thus are ultimately self-defeating.

In the 19th and 20th centuries the quantity theory played a part not only in analysis of inflation and business cycles but also in analysis of foreign exchange rates. The doctrine of purchasing-power parity, as developed primarily by Gustav Cassel, emphasizes that monetary expansion within a single country results in domestic price inflation. The inflation of prices, in turn, implies a decline not only in the internal purchasing power of the currency but also in the purchasing power of the inflated currency over money balances of other countries. The corrective for a depreciating exchange rate is stabilization of the supply of money and of the domestic level of prices.

Attacks on the Theory.—As the result of alleged failures of monetary expansion in the 1930s to promote full economic recovery, and also as the result of the doctrines of John Maynard Keynes (*q.v.*), monetary theory deviated sharply from quantity-theory tradition. Into the 1950s the prevalent view among economists was that monetary expansion is ineffective in reversing deflation, and that monetary restraint is effective but inefficient in control of inflation. The quantity theory's proportional relationship between money and the price level was dismissed as a special and improbable case.

During the 1950s the attack on quantity theory was extended. A theory of cost-push inflation evolved; it held that a rise in the price level may occur without monetary cause and that the supply of money must be increased as inflation occurs in order to prevent unemployment and a shrinkage in production of goods and services at the rising prices. A theory of structural inflation took another tangent, that inflation is a necessary aspect of economic growth, especially in some underdeveloped countries, and that money supply must be adapted to the advance in prices. These heresies against quantity-theory tradition attracted a wide following among economists. Dissenting less radically from quantity theory, other economists argued that financial development destabilizes V and h . Their view was that evolution of substitutes for money weakens or breaks the link between money supply and prices in the long run, between money supply and production in shorter intervals.

A reversion to quantity theory became apparent in the 1960s. Experience with postwar inflations, obvious successes of monetary restraint in curbing inflation, and new empirical studies of money and prices restored a degree of quantity theory's lost prestige. Formulation of the theory gained in sophistication with regard both to the supply of and demand for money. Correspondingly there was a revival of faith in monetary policy, as distinct especially from fiscal policy, for regulating aggregate money spending, demand for goods and services, and the levels of employment and prices.

QUANTUM MECHANICS is the mathematical system for describing the behaviour of such aspects of physics as light, molecules, atoms, and subatomic particles; it is the outgrowth of the quantum concept that all forms of energy (*q.v.*) are released in discrete units or bundles called quanta. Although much of this presentation is purely descriptive, certain portions assume some sophistication in such branches of mathematics as differential equations and matrix theory; a thorough understanding of the article MECHANICS is a minimum prerequisite for understanding this discussion in detail. Following are the main sections and divisions of this article:

I. INTRODUCTION

Throughout the 19th century most physicists regarded Newton's dynamical laws as sacrosanct. During the 20th century, however, it became increasingly clear that many phenomena, especially those connected with radiation, defy explanation on Newtonian principles. It is well recognized that two major innovations are essential. One of these is the introduction of the principle of relativity. The relativistic corrections are important only for bodies moving with velocities comparable to that of light, and as a result experimental confirmation is possible only in very special types of laboratory experiments or in the cosmological field. The other innovation is quantum mechanics. Although rather less publicized than relativity, the quantum concepts have equally drastic philosophical implications and furnish richer and more diversified fields for investigation in the laboratory.

Quantum mechanics is the mechanics governing phenomena which are so small-scale that they cannot be described in classical terms. Thus quantum rather than Newtonian dynamics must be used in dealing with the motions of electrons or nuclei inside atoms and molecules. In the equations of quantum mechanics, Max Planck's constant of action $h = 6.625 \times 10^{-27}$ erg sec. plays a central role. This constant, which is one of the most important in all of physics, has the dimensions

$$\text{mass} \times \text{length}^2/\text{time}$$

The term "small-scale" used to delineate the domain of quantum mechanics should not be literally interpreted as relating necessarily to extent in space. A more precise criterion as to whether quantum modifications of the Newtonian laws are of importance is whether or not the phenomenon in question is characterized by an "action" (time integral of the kinetic energy) which is large

compared to Planck's constant. Thus, if a great many quanta are involved, the Planck idea that there is a discrete, indivisible quantum unit loses importance, just as to a millionaire it would make little difference whether the smallest unit of currency is the cent or the dollar. This fact explains how the ordinary physical processes appear to be so fully in accord with the laws of Newton. Planck's element of action is, for example, far too fine-grained to have any bearing on the driving of an automobile. Since all matter seems to be built out of atomic or small-scale ingredients, it must be possible to describe the properties of even large-scale bodies by means of quantum mechanics. In other words, Newtonian dynamics must represent a special case of quantum dynamics appropriate to cases where the action is very large compared to the elementary quantum. This indeed seems true; it should be emphasized, however, that quantum mechanics is really an extension of classical statistical mechanics rather than of the deterministic laws of Newton. As a result, one of the most important philosophical implications of quantum mechanics concerns the apparent breakdown of the causality principle in atomic phenomena. (See *Uncertainty Principle*, below.)

The history of quantum mechanics may be divided into three main periods. The first of these began with Planck's theory of black-body radiation in 1900, and may be described as the period in which the validity of Planck's constant of action was demonstrated, but its real meaning was rather obscure. The second period began with the Bohr quantum theory of spectra in 1913. Niels Bohr's ideas gave an accurate formula for the frequency of spectral lines in many cases, and were an enormous help in the codification and understanding of spectra. Still they did not represent a consistent, unified theory, as he himself recognized, but rather a sort of patchwork affair in which classical mechanics was subjected to a rather extraneous set of so-called "quantum conditions," which restrict the constants of integration to certain particular values. The true quantum mechanics appeared in 1926, reaching fruition almost simultaneously in a variety of forms; viz., the matrix theory of Max Born and Werner Heisenberg, the wave mechanics of Louis V. de Broglie and Erwin Schrödinger, and the transformation theory of Paul A. M. Dirac and Pascual Jordan. These different formulations are in no sense alternative theories, but are different aspects of a consistent body of physical law.

Near mid-20th century the status of quantum mechanics was aptly described as follows (from Dirac in *Proceedings of the Royal Society, A*, vol. cxxiii):

The general theory of quantum mechanics is now almost complete, the imperfections that still remain being in connection with the exact fitting in of the theory with relativity ideas. These give rise to difficulties only when high-speed particles are involved, and are therefore of no importance in the consideration of atomic and molecular structure, and ordinary chemical reactions. . . . The underlying laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the exact solution of these laws leads to equations much too complicated to be soluble.

It should be added that conventional quantum mechanics makes no pretense of describing completely what goes on inside the nucleus. In other words, the details of the short-range dynamics of the particles of which the nucleus is composed are not precisely known, although quantum mechanics has been a help in understanding many nuclear phenomena, such as the emission of alpha particles and photodisintegration, and although the rather intricate field theory of quantum mechanics has provided some insight into the properties of mesons, transient particles which are of interest mainly in connection with nuclear phenomena. In short, by the 1960s the theory of nuclear physics was in a more or less embryonic stage comparable, say, with extranuclear quantum theory in its early days.

Thus, quantum mechanics gives appropriate laws of nature down to distances of the order 10^{-10} cm., but the rules are not known in detail below nuclear radii of the order 10^{-12} cm.

II. QUANTUM THEORY PRIOR TO THE BOHR ATOM

First will be described the earlier investigations in quantum theory which anteceded the discovery of the true quantum me-

chanics in 1926. This procedure is not merely an attempt to preserve historical order, but is also advisable because some of the primitive theories describe some subjects fairly well and help in the visualization of the later, more recondite developments.

1. Black-Body Radiation.—The quantum of action had its birth in the studies of black-body radiation in 1900 by Planck, professor of physics at the University of Berlin. All black (*i.e.*, perfectly absorbing) bodies heated to a given temperature should emit radiation having the same spectrum. The latter can be shown to be identical with the spectral distribution of energy in a so-called *Hohlraum*; *i.e.*, a cavity whose radiation is in thermal equilibrium with matter. (See **BLACK BODY**.) According to classical physics, the density of radiant energy should be proportional to the square of the frequency, and should increase without limit as the wavelength is made progressively shorter. This prediction is sometimes called the ultraviolet catastrophe, and the corresponding analytical formula for the energy density is called the Rayleigh-Jeans law. It yields the dashed curve of fig. 1. The observed distribution is that indicated by the solid curve, which Planck was able to deduce theoretically by making a quantum hypothesis.

FIG. 1.—THE ENERGY DENSITY (ρ_v) OF BLACK-BODY RADIATION AS A FUNCTION OF FREQUENCY (ν). CLASSICAL AND QUANTUM THEORIES GIVE RESPECTIVELY THE DASHED AND SOLID CURVES

We shall now indicate how the Rayleigh-Jeans and Planck radiation laws can be derived and shall formulate them mathematically. The method which we sketch is a well-known but rather formal one. It may be characterized as the application of classical equipartition (*see KINETIC THEORY OF MATTER*) or of classical statistics to the degrees of freedom of the ether. It is not presumed that a material ether really exists; this term is used merely to indicate that the standing electromagnetic waves in an enclosure are handled by the same type of statistical procedure as those of a material medium. The first step is the enumeration of the different types of standing waves or modes of vibration of the ether in a rectangular parallelepiped of volume V . Just as a rope with fixed ends can vibrate only in certain ways, represented by the fundamental and the various harmonics, so also in the three-dimensional case only certain modes of oscillation are compatible with the boundary conditions. If the edges of the parallelepiped are large compared to the wavelength, the number of possible vibrations in the frequency interval $(\nu, \nu + d\nu)$ can be shown to be

$$(8\pi\nu^2 V/c^3) \cdot d\nu \quad (1)$$

where c is the velocity of light. Let the mean energy of an oscillation of frequency ν be denoted by ϵ_ν . Then the density of radiant energy in the frequency range $(\nu, \nu + d\nu)$ is $\rho_\nu d\nu$ with

$$\rho_\nu = \epsilon_\nu \cdot (8\pi\nu^2/c^3) \quad (2)$$

It is now necessary to evaluate ϵ_ν . This is done by treating each characteristic mode of vibration as a harmonic oscillator. According to classical statistical mechanics,

$$\epsilon_\nu = kT \quad (3)$$

where k is Boltzmann's constant 1.38×10^{-16} erg/degree. Equation (3) is a direct consequence of the classical theory of equipartition. The latter demands that the mean kinetic energy per degree of freedom be $\frac{1}{2}kT$, and a harmonic oscillator has equal mean kinetic and potential energies, so that the total energy is kT . Substitution of (3) in (2) yields the Rayleigh-Jeans law

$$\rho_\nu = 8\pi\nu^2 kT/c^3 \quad (4)$$

The fact that ρ_ν increases without limit when ν is made arbitrarily large is the ultraviolet catastrophe mentioned above.

In quantum theory, however, the mean energy of a harmonic oscillator is taken to be

$$\epsilon_\nu = \frac{h\nu}{e^{h\nu/kT} - 1} \quad (5)$$

This formula is obtained by assuming that the energy of a harmonic oscillator is restricted to the "quantized" values $0, h\nu, 2h\nu, 3h\nu, \dots$. The mean energy is calculated by weighting these values in accordance with the usual Boltzmann factor, so that

$$\epsilon_\nu = \frac{h\nu e^{-h\nu/kT} + 2h\nu e^{-2h\nu/kT} + \dots}{1 + e^{-h\nu/kT} + e^{-2h\nu/kT} + \dots} \quad (6)$$

The series in the numerator and denominator of (6) are readily summed, and the result is (5). Substitution of (5) in (2) gives

$$p_\nu = \frac{8\pi h\nu^3}{c^3} \cdot \frac{1}{e^{h\nu/kT} - 1} \quad (7)$$

This is the celebrated Planck radiation formula. This represents essentially one approach used by Planck. He also had other ways of obtaining his formula, but most of these have been discarded. The best present derivation of the Planck radiation formula is probably one made by Albert Einstein in 1916, which is based on so-called detailed balancing for a system of matter and radiation.

2. Specific Heats.—Another early success of quantum theory was in the field of specific heats, where it explained the deviations from the law of P. L. Dulong and A. T. Petit. This law states that the specific heat per gram atom is very nearly the same, about six calories, for many solid elements. However, there are many exceptions. Also, if the temperature is lowered sufficiently, the specific heat approaches zero, instead of remaining constant, as predicted by the law. The behaviour of three metals, for instance, is shown in fig. 2. The law of Dulong and Petit is a direct consequence of the classical theory of equipartition, pro-

Hooke's law, the vibrations are simple harmonic. The dynamical system represented by the aggregate of atoms constituting the solid obviously is exceedingly complicated, but, in principle, modes of vibration can be sorted out according to frequency. Let there be $n_\nu d\nu$ such modes in the interval $(\nu, \nu + d\nu)$. Let the mean energy of a harmonic vibration be denoted by ϵ_ν , which, as before, has the value (3) or (5) depending on whether classical or quantum theory is used. The total energy is obtained by integrating over all frequencies, and the specific heat c_V is the temperature derivative of the energy. Hence

$$c_V = \frac{d}{dT} \left[\int_0^\infty n_\nu \epsilon_\nu d\nu \right] \quad (8)$$

The determination of the factor n_ν , specifying the distribution of vibration frequencies represents an exceedingly difficult problem, as n_ν is no longer given by the simple expression (1) which applied in the radiative case. However, if the classical result $\epsilon_\nu = kT$ is employed, it is not necessary to determine n_ν , as kT is merely a constant factor, which can be taken outside the integration. The integral can then be immediately evaluated from the relation

$$\int_0^\infty n_\nu d\nu = 3N \quad (9)$$

which states that the total number of independent modes of oscillation (*i.e.*, the total number of degrees of freedom) must be three times the total number of atoms N . Hence, according to classical equipartition,

$$c_V = 3Nk \quad (10)$$

This is essentially the law of Dulong and Petit. If we take an amount of material equal to a gram atom, so that N becomes the Avogadro number, and if we express the specific heat in calories rather than in ergs, then (10) gives a specific heat of 5.96 cal. per degree.

In quantum theory, on the other hand, it is necessary to evaluate n_ν . Peter J. W. Debye assumed a distribution law for n_ν , analogous to that (1) for the radiative case, but with allowance for transverse and longitudinal vibrations with different velocities of propagation, which can be calculated from the elastic constants of the material. There is then no limit to the high-frequency end of the spectrum, and the integrals in (8) and (9) diverge. To avoid this difficulty the upper limit in (8) and (9) is rather artificially taken to be ν_0 rather than ∞ , where ν_0 is a cutoff frequency so chosen as to satisfy (9) and thus make the total number of vibrations equal to $3N$. With this model, Debye found $c_V = f(T/T_0)$, where $f(T/T_0)$ is a universal function of a reduced temperature T/T_0 , which is the ratio of the ordinary temperature to a so-called characteristic temperature T_0 , calculable from the elastic properties of the material. This reduced temperature is used for the abscissa in fig. 2. Debye's method for obtaining n_ν , originally appeared somewhat artificial but Born and Theodore von Kármán showed that it had some dynamical basis. The Debye model applies only to simple monatomic solids. When the solid is composed of molecules, it is necessary to consider the vibrations not only of molecules with respect to each other but also the vibrations of atoms inside the molecules. As emphasized by Einstein, the latter effect gives sharp maxima of n_ν at certain frequencies. Improved methods of calculating n_ν have been developed, and the theory correspondingly refined. So far only the solids have been mentioned. There is also considerable literature on the specific heats of gases. Here again, quantum theory explains deviations from the classical theory of equipartition, especially at low temperatures, which are particularly pronounced for hydrogen.

3. Photoelectricity.—Nowhere, perhaps, is the inadequacy of classical theory revealed more strikingly than in the subject of photoelectricity, which is concerned with emission of electrons by an illuminated body. (See PHOTOELECTRICITY.) Photoelectric phenomena exhibit two main features: (1) no emission occurs at all unless the frequency ν of the incident radiation exceeds a certain critical value, called the threshold frequency; and (2) the

ADAPTED FROM T. PRESTON, "THEORY OF HEAT" (MACMILLAN)

FIG. 2.—SPECIFIC HEAT OF A MONATOMIC SOLID AS A FUNCTION OF TEMPERATURE. THE CURVE IS CALCULATED FROM DEBYE'S QUANTUM THEORY. THE SCALE OF ORDINATES IS SO CHOSEN THAT CLASSICAL THEORY GIVES UNITY

vided the latter is applied to the atom as a whole and no attempt is made arbitrarily to apply classical statistics to the motion of the electrons inside the atom. The specific heat is then independent of temperature, and so in fig. 2 would be represented by a horizontal straight line of unit height in the scale employed there. Debye's quantum model, on the other hand, yields the solid curve, which is in good agreement with experiment. This curve approaches unity if the temperature is raised sufficiently. More generally, all classical and quantum theories of specific heats agree asymptotically at high temperatures. On the other hand, the vanishing of the specific heat at the absolute zero is a characteristic quantum phenomenon.

In the mathematical analysis the difference between the classical and quantum theories of the specific heats of solids parallels closely that between the proofs of the Rayleigh-Jeans and Planck laws for radiation. Instead of considering the electromagnetic vibrations of the ether, it is necessary to deal with the vibrations of the atoms composing the solid with respect to each other. If the forces binding the atoms to their equilibrium positions obey

kinetic energy of the ejected electrons depends on the frequency of this radiation, and not on its intensity. In other words, if a light source is removed farther and farther from the body which it illuminates, the emitted electrons are undiminished in their velocity of escape, but are decreased in number. Such a state of affairs was a complete conundrum at the end of the 19th century, since in classical electromagnetic theory, diminished incident intensity implies a lowering of the energy traversing the absorbing target area, and thus as a result of the lower energy flow, the velocity imparted to the electron should be decreased, contrary to experiment. In 1905 Einstein showed that the observed behaviour could be explained if in the emission of the electron a quantum of energy $h\nu$ is picked up by matter from the radiation, regardless of the latter's intensity. The process merely becomes less likely when the intensity is low. Just how such a corpuscular model was to be reconciled with the undulatory features of light, such as interference, was something not understood for two decades or so, but was finally clarified by the Heisenberg uncertainty principle and by Bohr's theory of complementarity. From the less sophisticated outlook of 1905, Einstein showed that if the conflict with the wave viewpoint was ignored, his picture did indeed account for the salient factors of photoelectricity. The kinetic energy of escape of the electron will not in general be the same as the quantum $h\nu$ absorbed from the radiation inasmuch as part of the energy is consumed in liberating the electron from the metal. This portion is called the thermionic work function, and will be denoted by the letter ϕ . Einstein's equation for determining the velocity of escape v of an electron is thus

$$\frac{1}{2}mv^2 = h\nu - \phi \quad (11)$$

Since the kinetic energy $\frac{1}{2}mv^2$ is necessarily positive, emission is possible only if $\nu > \phi/h$. Hence ϕ/h is the threshold frequency.

Closely related to the photoelectric effect is the Compton effect (*q.v.*), which also reveals the need of the quantum hypothesis.

III. BOHR ATOM

A signal advance in quantum theory was achieved when the Danish physicist Niels Bohr propounded his theory of the spectrum of hydrogen, in 1913. By that time there was confidence as to the validity of the Rutherford picture of the atom as a miniature solar system, with the nucleus and electrons playing respectively the role of the sun and the planets. (See ATOM.) The number of electrons in the neutral atom is the same as the chemists' atomic number, one for hydrogen, two for helium, etc. Therefore, the dynamics of the orbits of the electrons in the various atoms will be very complex except in the hydrogenic case, for the mathematical difficulties associated with even a three-body problem (*e.g.*, neutral helium, with one nucleus and two valence electrons) are enormous. By a hydrogenic atom is not necessarily meant a hydrogen atom, but any other atom which has been stripped of all but one valence electron as a result of ionization. Examples are singly ionized helium, doubly ionized lithium, etc. Clearly, the study of the spectrum of hydrogen, because of its comparative simplicity, should be the most likely starting point of any attempt to decipher the complexities of atomic spectra.

1. Balmer Formula.—It has long been known that there are some remarkable regularities in the spectrum of hydrogen. As early as 1885, J. J. Balmer showed that the wavelengths λ of many lines are well represented by the empirical formula

$$\frac{1}{\lambda} = RZ^2 \left[\frac{1}{n'^2} - \frac{1}{n''^2} \right] \quad (12)$$

in which n' , n'' are integers, and R is a constant, the so-called Rydberg constant. If, for instance, one takes $n' = 2$ and $n'' = n' + 1$, $n' + 2$, \dots , the expression (12) gives the wavelengths of the lines in what is called the Balmer series. The choices $n' = 1$, 2, 3, 4 and 5 yield respectively the Lyman, Paschen, Brackett and Pfund series, which were discovered later. Since the atomic number Z is unity for hydrogen, the factor Z^2 in (12) is unnecessary for present purposes, but is included to permit later extension to atoms of higher nuclear charge.

2. Postulates of the Bohr Theory.—For many years, the *raison d'être* for the formula (12) was completely obscure. It is not surprising that the subject of line spectra was a closed book to the classical physicist. As some one has said, the task of constructing a model of the atom merely from knowledge of its spectra radiated under violent electrical or thermal excitation is comparable with trying to learn about a piano merely from the noise emitted when it is dropped downstairs. Bohr, however, showed that the behaviour (12) could be explained by means of two postulates, as follows:

1. The existence of stationary states: In every atom there is a discrete succession of states, in any one of which the electrons can move without appreciable radiation, and which can be identified by a set of integers, usually called quantum numbers. The designation of these states as stationary refers to the absence of radiation from the orbits, in contravention of classical electrodynamics, and does not imply a static atom. Except for omission of the radiation corrections, the motion of the electrons in the stationary states is assumed to conform to the laws of classical mechanics.

2. The Bohr frequency condition: It is assumed that an electron can sometimes pass discontinuously from one allowed orbit to another. In such a transition, the initial and final states will have different amounts of mechanical energy E'' and E' . To secure conservation of energy, the change in the mechanical energy must be counterbalanced by the absorption or emission of a light quantum, whose energy is $h\nu$ if the frequency is ν . This requirement yields the so-called Bohr frequency condition

$$h\nu = E'' - E' \quad (13)$$

The analogy to Einstein's photoelectric equation (11) should be noted.

In connection with the first postulate it is necessary to formulate the quantum conditions which restrict the energies of the atoms to certain particular values. The easiest case to handle is that of a simply periodic system, where the orbit repeats itself after a given interval of time τ . Here the quantization is effected by the relation

$$\bar{T} = \frac{1}{2}nh\nu_0 \quad (14)$$

in which n is an integer, \bar{T} is the mean kinetic energy of the system (*i.e.*, the average of the kinetic energy T over a period) and $\nu_0 = 1/\tau$ is the frequency with which the orbit repeats itself. It is to be emphasized that the orbital frequency ν_0 is in general not the same as that ν given by the Bohr frequency condition (13). This nonidentity of the orbital and radiated frequencies is a celebrated paradox of the Bohr atom, as according to classical mechanics or actual observations on large-scale phenomena there is no distinction between the frequencies of motion of a system and those of the waves which it radiates. It should be mentioned, however, that in the Bohr theory there is an asymptotic agreement of the two frequencies for large quantum numbers, which is usually termed the "correspondence principle for frequencies."

3. Derivation of the Balmer Formula From the Bohr Theory.—It will now be shown that the Balmer expression (12) is a consequence of the quantum condition (14) and the Bohr frequency condition. This derivation is such a simple and classic one that it seems worth giving, even though in a sense it is outmoded by later but more intricate calculations by means of wave mechanics, which also yield the result (12) with identically the same value of the Rydberg constant R as that obtained from the Bohr theory.

To simplify the calculations, it will be assumed that the orbit is circular, but it can be shown that the energy levels are no different in the general case of ellipses. Let the mass of the nucleus and electron be denoted by M and m respectively, and let the nuclear and electronic charges be Ze and $-e$. Here e has the value 4.80×10^{-10} in electrostatic units, and Z is the atomic number. The centre of gravity, which may be supposed stationary, divides the line connecting the two particles in the inverse ratio of their masses. Hence, the electron and nucleus

revolve around this centre in circles of radii $Ma/(m+M)$ and $ma/(m+M)$ respectively, where a is the distance from the nucleus to the electron. Since the angular velocity is $2\pi\nu_0$, the kinetic energy is

$$T = \frac{1}{2} \left[m \left(\frac{M}{m+M} \right)^2 + M \left(\frac{m}{m+M} \right)^2 \right] (2\pi\nu_0)^2 a^2 \quad (15)$$

This equation can also be written as

$$T = \frac{1}{2} \mu (2\pi\nu_0)^2 a^2 \quad (16)$$

where μ is the so-called reduced mass, given by

$$\mu = mM/(m+M) \quad (17)$$

As T is constant in time, there is no distinction between T and \bar{T} . Thus application of the quantum condition (14) gives

$$(2\pi\nu_0)\mu a^2 = nh/2\pi \quad (18)$$

In other words, the angular momentum of the system is an integral multiple of $h/2\pi$. The equality between the centrifugal force on the electron and the Coulomb attraction due to the nucleus yields a further relation

$$\mu a (2\pi\nu_0)^2 = Ze^2/a^2 \quad (19)$$

When equations (18) and (19) are solved for a and ν_0 , the result is

$$a = n^2 h^2 / 4\pi^2 Z^2 e^2 \mu \quad \nu_0 = 4\pi^2 \mu Z^2 e^4 / n^3 h^3 \quad (20)$$

The first relation of (20) shows that the allowed (*i.e.*, quantized) values of the radius of the atom form a progression of the form $a_0, 4a_0, 9a_0, \dots$, where a_0 is a fundamental unit $h^2/4\pi^2 \mu Z e^2$ called the Bohr radius, and having the numerical value 0.53×10^{-8} cm. if $Z = 1$ (hydrogen). Substitution of (20) in (16) gives

$$T = 2\pi^2 \mu Z^2 e^4 / n^3 h^3$$

while the potential energy is

$$V = -Ze^2/a = -4\pi^2 \mu Z^3 e^4 / n^3 h^3$$

Hence the total energy $E = T + V$ is

$$E = -2\pi^2 \mu Z^2 e^4 / n^3 h^3 \quad (21)$$

When we substitute this value of E in the Bohr frequency condition (13) and remember that $\lambda = c/\nu$, we have indeed the Balmer formula (12), provided the Rydberg constant R has the value

$$R = 2\pi^2 \mu e^4 / ch^3 \quad (22)$$

The question immediately arises whether (22) yields a value of R in agreement with the optical measurements, when the numerical values of the constants e, h, μ, c are substituted. The answer is that there is certainly agreement within the precision with which these constants are known, for e, h, μ are known only to 1 part in 10,000 or so. On the other hand, since optical wavelengths are known so very accurately, the Rydberg constant R can be determined to within less than 1 part in 1,000,000. A valuable cross-check on the values of the various atomic constants is thus provided: namely, use of (22) along with the spectroscopic determination of R permits determination of one of the four quantities e, h, μ, c if the other three are known. It is thus possible to increase the accuracy with which the value of the particular one of the four constants is known (*viz.*, h) which otherwise cannot be as precisely determined as the other three.

4. Correction for the Motion of the Nucleus, and Spectroscopic Determination of e/m .—If we neglect the motion of the nucleus, or in other words consider the mass M of the nucleus to be infinite, then equation (17) shows that the reduced mass becomes identical with the mass m of the electron. When allowance is made for the finite mass of the nucleus, μ will differ slightly from m . The neutral hydrogen atom and ionized helium atom resemble each other in having only one electron, so that formula (22) should be applicable to either. However, the different masses of the hydrogen and helium nuclei will make the Rydberg constant slightly different for the two. Just this state

of affairs is found experimentally: the best spectroscopic value of the Rydberg constant for hydrogen is $R_H = 109677.58$ cm.⁻¹, while that for helium is $R_{He} = 109722.27$ cm.⁻¹ (J. W. M. Du Mond and E. R. Cohen). The corresponding value for a hydrogenic atom of infinite nuclear mass is $R_{H\infty} = 109737.31$ cm.⁻¹.

Equation (22) shows that the ratio of the Rydberg constants for hydrogen and ionized helium is equal to the ratio of the reduced masses, the other constants canceling out. When (17) is used,

$$\frac{R_{He}}{R_H} = \frac{1 + m/M_H}{1 + m/xM_H} \quad (23)$$

where x is the ratio M_{He}/M_H of the mass of the helium nucleus to that of hydrogen. This ratio can be regarded as known from determinations of atomic weights, since practically all of the atom's mass arises from the nucleus. Hence, by means of (23) and the spectroscopic determinations of R_H, R_{He} , it is possible to evaluate the ratio m/M_H of electronic to protonic mass. Furthermore, it is possible to go a step further and determine e/m spectroscopically, inasmuch as one has $e/m = (e/M_H)(M_H/m)$ and as the value of e/M_H is known from electrolysis; *i.e.*, from the so-called electrochemical equivalent. In this way, the shift between the Rydberg constants for hydrogen and ionized helium furnishes perhaps the most accurate means of determining e/m . In the early 1930s there appeared to be a discrepancy between the values of e/m determined spectroscopically and by more direct deflection methods. This difficulty has disappeared, and the generally accepted value of e/m is 1.759×10^7 e.m.u.

During the first years of Bohr's theory, the only known hydrogenic atoms (*i.e.*, those with one valence electron) were H and He⁺. Subsequently, X-ray measurements at Uppsala, Swed., revealed lines due to Li²⁺, Be³⁺, B⁴⁺, and C⁵⁺. These lines are particularly useful because they furnish wavelength standards in the X-ray region. Another subsequent development was the discovery of the hydrogen isotope deuterium, which has about double the value of M for ordinary hydrogen and hence a slightly different Rydberg constant. This difference, in fact, historically furnished the first means of demonstrating the existence of deuterium with certainty.

5. Relativity Fine Structure.—A great triumph of the Bohr atom was the theory of the relativity fine structure in hydrogen, which was developed by Arnold Sommerfeld in 1916. In the preceding discussion, the problem was treated by means of Newtonian mechanics. When the relativity corrections are introduced, the orbits cease to be periodic, and the quantization becomes more complicated. It is necessary to introduce two quantum conditions, mathematical details of which will be omitted here except for mentioning that they restrict the values of certain so-called "phase integrals" to integral multiples of Planck's constant. If the nuclear mass is treated as infinite, the formula for the energy can be shown to be

$$E = mc^2 \left\{ \left[1 + \left(\frac{\alpha Z}{n - k + g} \right)^2 \right]^{-1/2} - 1 \right\} \quad (24)$$

where

$$\alpha = 2\pi e^2 / hc \quad g = (k^2 - Z^2 \alpha^2)^{1/2} \quad (25)$$

If (24) be expanded as a power series in α^2 , and terms beyond α^4 are disregarded, the expression for E takes the form

$$E = -\frac{2\pi^2 m Z^2 e^4}{n^3 h^3} \left[1 + \frac{\alpha^2 Z^2}{n^2} \left(\frac{n}{k} - \frac{3}{4} \right) + \dots \right] \quad (26)$$

Since $m = \mu$ if $M = \infty$, the first term of (26) is the same as the Newtonian result (21), and involves only the principal quantum number n . The remainder of (26) is due to the relativity corrections, and involves a second quantum number k , which is the so-called azimuthal quantum number. Its physical significance is that the angular momentum is $kh/2\pi$, and the range of values for k is 1, 2, \dots, n . The dependence of the energy on k is only a minor effect because of the smallness of α ($= 1/137.0$), but it causes lines which would otherwise coincide to be slightly separated so as to form the components of a multiplet. A decomposi-

tion is indeed found experimentally, and on the whole the observed spacing of the components agrees well with theory.

6. Stark Effect.—Still another quantitative success of the Bohr theory of the hydrogen spectrum is provided by the Stark effect, or splitting of the energy levels and hence of the spectral lines by means of an electric field. The separation and number of the components accords with theory in a remarkable fashion. The formulas for the displacement in frequency involve Planck's constant h , and so classical theory was powerless to explain any of the features of the Stark effect. On the other hand, in the alternative phenomenon of the Zeeman effect (separation of lines in a magnetic field), Planck's h cancels out of the final formula for the shift in frequency, and so classical and quantum theories give identical results for the normal Zeeman effect (*q.v.*).

7. Moseley's Relation.—In attempting to apply the Bohr concepts to nonhydrogenic atoms, the mathematical complexities are so great that the permitted energy levels or frequencies cannot be exactly determined. Nevertheless, certain successes of the theory should be stressed. One of these is the explanation of Moseley's relation in X-ray spectra, wherein the frequencies of the K lines—*i.e.*, the hardest lines (lines of shortest wavelength or highest frequency)—are proportional approximately to the square of the atomic number. This is simply an expression of the factor Z^2 in (21). The result (21) applies approximately to an interior electron of a nonhydrogenic atom if the screening of the nucleus by the other electrons is so poor that the field is substantially that of the bare nucleus. This approximation will be a good one only for electrons which are deep-seated in the atom, such as are responsible for the emission of X-rays.

8. Relation Between Critical Potentials and Spectral Frequencies.—By electron bombardment it is possible to "excite" an atom from one stationary state, say of energy E' , to another of higher energy E'' . To be able to do this, the impinging electron must have at least a kinetic energy equal to $E'' - E'$, as otherwise conservation of energy cannot be secured. The energy which an electron acquires in falling through a difference of potential V is eV . Hence, the minimum or "critical" accelerating potential required for the excitation is given by $eV = E'' - E'$. Alternatively, the Bohr frequency condition states that $h\nu = E'' - E'$. Thus, $eV = h\nu$, and this relation holds as a useful consequence of the theory, even though the mechanics of the many-body problem is so intricate that it is not possible to calculate theoretically the energy levels E', E'' .

9. Stern-Gerlach Effect.—The application of the quantum conditions to an atom in a magnetic field shows that its component of angular momentum in the direction of the field should be "quantized" and equal to an integral multiple of $h/2\pi$. The corresponding magnetic moment, which is proportional to the angular momentum, should hence likewise acquire only discrete values. Otto Stern and Walther Gerlach verified this prediction by observing the deflections of atoms in an inhomogeneous magnetic field. We cannot overemphasize how beautifully the existence of only certain particular deflections in their experiments offers evidence for the existence of the quantized positions which are the essence of quantum theory. It is clear that the explanation of the precise quantitative values of the deflections found by Stern and Gerlach requires inclusion of electron spin and the refinements of quantum mechanics in certain cases. However, the broad outlines of the phenomenon were sharp even in the days of the Bohr theory, especially the complete contradiction between the classical continuous distribution of orientations and quantum discreteness. The Stern-Gerlach experiment decided unequivocally in favour of the latter.

10. Harmonic Oscillator and Rotator—Molecular Spectra.—There are two very simple schematic models which are particularly easy to quantize and which are rich in physical applications. They are the harmonic oscillator and the rigid rotator or "rotating dumbbell."

For a particle which is harmonically bound (*i.e.*, subject to a linear restoring force) the mean kinetic energy is equal to the mean potential energy. Hence the total energy, which is the sum of the kinetic and potential, is equal to twice the mean kinetic

energy. Furthermore, the frequency ν_0 of a harmonic oscillator is independent of the initial conditions. Therefore, application of (14) immediately yields the result

$$E = nh\nu_0 \quad (27)$$

The quantized values of the energy of a harmonic system given in (27) are the same as those used above in discussing black-body radiation and specific heats.

For a rigid rotator, there is no potential energy, and the kinetic energy has the constant value $\frac{1}{2}I(2\pi\nu_0)^2$, where I is the moment of inertia, and ν_0 is the rotation frequency. The quantization condition (14) yields $2\pi\nu_0 I = nh/2\pi$. The quantization thus consists in equating the angular momentum to an integral multiple of $h/2\pi$. The corresponding quantized value of the energy is, since $E = T$,

$$E = n^2 h^2 / 8\pi^2 I \quad (28)$$

These formulas have a direct application to the spectrum of a diatomic molecule such as HCl. As a first approximation, the energy of the molecule can be divided into contributions from (1) the electronic motion relative to the two nuclei regarded as fixed attracting centres, (2) the vibration of the two nuclei along the line connecting them, and (3) "end-over-end" rotation of the molecule as a whole. Effects (2) and (3) are respectively portrayed by the harmonic oscillator and the rotator. The quantum numbers associated with (2) and (3) are not, of course, the same, and so the letters v, J are used for them instead of n . The total energy of the molecule is thus

$$E = E_0 + v h \nu_0 + J^2 h^2 / 8\pi^2 I \quad (29)$$

The electronic term E_0 will be a function of numerous quantum numbers other than v, J , but is too difficult to compute explicitly because of the complexities of the many-body problem. The dependence on the vibrational and rotational quantum numbers v, J predicted by (29) agrees nicely with experiment.

11. Intensities and Transition Probabilities in the Bohr Theory.—The theory so far presented is one-sided, as it tells how to calculate the frequency but nothing about the intensity. In order to have information about the latter, it is necessary to know the transition probability. It is a fundamental concept of the Bohr theory that radiation takes place sporadically and discontinuously, when an electron passes from one stationary state to another, rather than continuously as in classical theory. The transitions between states are governed by the statistics of random processes, like radioactive decay. Thus, if an electron is initially in a state l , there is a certain probability $A_{l \rightarrow m}$ that it will pass to another state m . Let us denote by $\nu(lm)$ the frequency associated with this transition, which by (13) is the same as $(E_l - E_m)/h$. Since an amount of energy $h\nu(lm)$ is radiated in each transition, the total rate at which energy is radiated in the frequency $\nu(lm)$ is

$$I_{l \rightarrow m} = h\nu(lm) A_{l \rightarrow m} N_l \quad (30)$$

where N_l is the number of atoms in the state l .

Part of the contribution to $A_{l \rightarrow m}$ in the case of emission, and all in the case of absorption, will come from transitions induced by a radiation field. Even in the absence of the latter, however, there is a certain probability of "spontaneous radiation," provided the energy E_m of the final state is less than that E_l of the initial one. For simplicity, only the spontaneous effect will be considered.

The problem is now to calculate the transition probability in the absence of a radiation field. Here the Bohr theory gave no clear-cut answer. The best that could be done was to make an approximate estimate by means of the so-called correspondence principle, which has been described as a "magic wand which enables one to borrow the results of classical theory for quantum theory." According to classical electrodynamics, an electron moving in a periodic orbit described by Fourier series such as

$$x = \sum_{r=-\infty}^{\infty} x_r e^{2\pi i r \nu_0 t}$$

radiates energy in the harmonic $\tau\nu_0$ at a rate

$$(4e^2/3hc^3)(2\pi\tau\nu_0)^4[|x_\tau|^2 + |y_\tau|^2 + |z_\tau|^2]$$

The correspondence principle for frequencies shows that if the difference in quantum number between the initial and final states is τ , the quantum frequency $\nu(lm)$ approaches asymptotically the classical overtone $\tau\nu_0$ if the quantum number is large. Hence, a formula by which the transition probability can be estimated qualitatively or asymptotically is

$$A_{l \rightarrow m} = (4e^2/3hc^3)(2\pi)^4\nu(lm)^3[|x_l - m|^2 + |y_l - m|^2 + |z_l - m|^2] \quad (31)$$

It is to be emphasized that (31) never gives a clear-cut and unambiguous answer, as there is no way of telling whether the Fourier coefficients should be evaluated for the initial or the final orbit of the transition, or should represent some sort of compromise between the two.

IV. ADVENT OF TRUE QUANTUM MECHANICS

Although the Bohr theory had the many triumphs indicated above, still as time progressed, especially in the early 1920s, it became increasingly apparent that it was not adequate. With much labour it was possible to determine the energy levels of the neutral helium atom, a three-body problem, and these did not accord with experiment. Unjustifiable half-quantum numbers (*i.e.*, half rather than whole integers) kept appearing in the empirical description of band spectra. Numerous other difficulties could be recited. It was clear that the trouble was simply that the traditional Bohr quantum theory was a patchwork doctoring of classical mechanics, wherein the quantum conditions were added in a rather artificial way. What was needed was a rational, self-consistent quantum mechanics, which started afresh and evolved a mathematical framework and philosophy all its own. This was discovered in 1926, which was thus an epoch-making year in the history of physics.

This remarkable new mechanics cannot be regarded as the product of any one man, and was instead the result of the impact of thinker on thinker among the leading theoretical physicists of the time. It was developed in a diversity of mathematical forms, which present a rather confusing array to the student beginning the subject. However, these various formulations, though different in superficial mathematical structure, are basically in harmony with each other.

The three main mathematical forms are the following: (1) the matrix theory of Born, Heisenberg and Jordan; (2) Schrödinger's wave mechanics, the outgrowth of De Broglie's concept of "phase waves"; and (3) the so-called transformation theory, based on kinetical indeterminism, developed by Dirac and Jordan, and interpreted by Heisenberg.

A. WAVE MECHANICS

1. Hamiltonian Analogy and De Broglie Waves.—We shall begin with the so-called wave formulation, as this is the version most universally used, and perhaps the easiest to understand. The impetus to the development of this form of quantum mechanics was furnished by De Broglie's interpretation of the classical Hamiltonian analogy between optics and dynamics. This analogy, which is readily demonstrated from Fermat's principle in optics and the principle of least action in mechanics, establishes a formal similarity between the path of the particle in a mechanical system and a hypothetical optical system in which the refractive index is correlated in a rather arbitrary way with the potential energy $V(x, y, z)$ in the mechanical problem. This comparison always seemed highly artificial because the velocity in the optical system was different from that in the mechanical one. However, if somehow it is possible to introduce the concept of wavelength into the analogy, so that it is meaningful to talk about dispersion, then besides the phase velocity there is also a group velocity, which is the velocity with which signals or modulations are propagated.

De Broglie showed that although the velocity of the mechanical particle differed from the phase velocity, it became identical with the group velocity, provided the wavelength has the value

$$\lambda = \frac{h}{\sqrt{2m(E - V)}} = \frac{h}{mv} \quad (32)$$

The second form of (32) is obtained by noting that the energy constant E is the sum of the kinetic energy $\frac{1}{2}mv^2$ and the potential energy $V(x, y, z)$. Formula (32) gives the celebrated De Broglie wavelength which occurs so characteristically in quantum-mechanical diffraction problems. When De Broglie first propounded his ideas in 1925, it was not clear whether they had much physical significance, but only a year or so after his paper, the existence of the De Broglie wavelength was confirmed in a most striking fashion in the experiments of Clinton J. Davisson and Lester H. Germer on the diffraction of electrons by a crystal. They showed that beams of electrons passing through a crystal were diffracted in many ways like X-rays, but with the wavelength given by the formula $\lambda = h/mv$.

2. Schrödinger Wave Equation.—Prior, however, to the Davisson-Germer experiments, Schrödinger recognized the great portent of the De Broglie wavelength, and by means of it was led to the fundamental equation of wave mechanics, usually called the wave equation. Schrödinger conjectured that true quantum mechanics stands in the same relation to ordinary classical mechanics that physical optics does to geometrical optics. Just as the ray-tracing characteristic of the latter fails in explaining the phenomena of diffraction and interference, so, Schrödinger reasoned, ordinary mechanics could not explain atomic phenomena, the reason in each case being that the dimensions are not large compared to the wavelength. Hence he sought to establish a procedure analogous to that used in physical optics, in which the fundamental wave equation is

$$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = \frac{1}{u^2} \frac{\partial^2 f}{\partial t^2} \quad (33)$$

Here the phase velocity u may be a function of x, y, z . In the monochromatic, or periodic, case, the solutions can be written in the form $f = \psi(x, y, z)e^{2\pi i\nu t}$, where the space factor ψ satisfies the equation

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} + \frac{\partial^2 \psi}{\partial z^2} = \frac{4\pi^2}{\lambda^2} \psi \quad (34)$$

with $\lambda = u/\nu$. For the wavelength λ , Schrödinger inserted the De Broglie value (32). Then (34) becomes

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} + \frac{\partial^2 \psi}{\partial z^2} + \frac{8\pi^2 m}{h^2} (E - V) \psi = 0 \quad (35)$$

This is the Schrödinger wave equation. One immediately wonders how quantized phenomena can be extracted from (35), as a partial differential equation suggests things continuous rather than discrete. The answer is that one must confine one's attention to so-called physically admissible, or, colloquially, "civilized" solutions of (35), which meet certain requirements of continuity, single-valuedness, etc. Solutions which fulfill these demands are called characteristic functions, proper functions or eigenfunctions. The precise conditions that these physically admissible solutions need to meet vary somewhat with the physical nature of the problem. It is usually sufficient that ψ be single-valued, continuous, together with its first derivatives, and finite, except perhaps at a few points at which ψ becomes infinite in such a way that

$$\iiint |\psi|^2 dv \text{ and } \iiint \left\{ \left| \frac{\partial \psi}{\partial x} \right|^2 + \left| \frac{\partial \psi}{\partial y} \right|^2 + \left| \frac{\partial \psi}{\partial z} \right|^2 \right\} dv$$

exist. Also, ψ must vanish at infinity. Now, to be sure, (35) possesses an infinity of solutions, since the latter involve arbitrary constants of integration and even arbitrary functions. Nevertheless, it often happens that not one of these solutions has the properties demanded of a characteristic function. Instead, an admissible solution is usually obtained only if E is given certain particular values, called characteristic values, proper values or eigenvalues. These values of E are those which are to be substituted into the Bohr frequency condition (13).

3. Rotator and Harmonic Oscillator.—A simple illustration of how the condition that the solution be physically admissible

sible limits the parameter E is provided by the two-dimensional rotator; i.e., the rotating dumbbell whose motion is confined to a plane. Here the wave equation analogous to (35) is given by the expression

$$\frac{\partial^2 \psi}{\partial \varphi^2} + \frac{8\pi^2 I E}{h^2} \psi = 0 \quad (36)$$

as is seen by specializing (35) to one co-ordinate, with $V = 0$, and noting that in a rotational problem the moment of inertia I and angle φ replace the mass and a linear displacement. The solution of (36) is

$$\psi = A \cos[(8\pi^2 I E / h^2)^{1/2} \varphi - \epsilon] \quad (37)$$

where A and ϵ are arbitrary constants. The requirement of single-valuedness as a function of position on the circular path of rotation demands that $\psi(\varphi + 2\pi) = \psi(\varphi)$. This is possible only if the coefficient of φ in the argument of the cosine is an integer n . Thus

$$E = n^2 h^2 / 8\pi^2 I \quad (38)$$

This is exactly the same formula for the energy of a rotator as that (cf. equation [28]) obtained with the old quantum theory. It would thus at first appear that the new quantum mechanics did not remove the difficulty that half rather than whole integers are required to obtain agreement with experiment on rotational energy levels. Actually, however, the end-over-end rotation of a molecule should be represented by a rotator not confined to a particular plane, and so associated with a three- rather than two-dimensional space. When this extra degree of freedom is added, it is found that the factor n^2 in (38) is replaced by $(n + \frac{1}{2})^2 - \frac{1}{4}$, so that, apart from an unimportant additive constant, the result is the same as though half quantum numbers were used in the Bohr theory. Details of the analysis are omitted here, but it is essentially the same as that in classical potential theory where it is shown that the characteristic values of the differential equation for surface harmonics are proportional to $n(n + 1)$.

Of course, in most problems the mathematical analysis is more complicated than in this purposely simple illustration of the rotator. When exact, closed expressions are obtained for the characteristic values of a system with one degree of freedom, they are usually derivable by the so-called polynomial method. In this, the solution is expressed as a power series, and it is shown that if the series does not terminate, the solution is not physically admissible. The termination condition then usually restricts the energy parameter E to certain particular or so-called characteristic values.

The polynomial method may be illustrated by the one-dimensional harmonic oscillator. Here the wave equation (35) takes the form

$$\frac{d^2 \psi}{dx^2} + \frac{8\pi^2 m}{h^2} (E - \frac{1}{2} \alpha x^2) \psi = 0 \quad (39)$$

On the introduction of the following abbreviations and changes of variable,

$$A = \frac{4\pi E}{h} \left(\frac{m}{\alpha}\right)^{1/4}, \quad u = \frac{m^{1/2} \alpha^{1/4} (2\pi)^{1/4}}{h^{1/4}} x, \quad \psi = e^{-u^2/2} g \quad (40)$$

equation (39) becomes

$$\frac{d^2 g}{du^2} - 2u \frac{dg}{du} + (A - 1)g = 0 \quad (41)$$

A series solution is assumed:

$$g = c_0 u^0 + c_2 u^2 + c_4 u^4 + c_6 u^6 + \dots \quad (42)$$

After the indicated operations are performed, the entire left side of (41) can be expressed in the form of a series. The coefficient of each power of u in the latter must vanish if (41) is satisfied. The vanishing of the coefficient of the lowest power (viz., u^0) requires either $k = 0$ or $k = 1$. On equating to zero the coefficient of u^n , one obtains the recurrence formula

$$\frac{c_{n+2}}{c_n} = \frac{2n + 1 - A}{(n + 1)(n + 2)}$$

for determining the ratio c_{n+2}/c_n . The series (42) will terminate at the term $c_n u^n$ if $A = 2n + 1$ or, in other words, by (40) if

$$E = (n + \frac{1}{2}) h \nu_0 \quad \text{with} \quad \nu_0 = \frac{1}{2\pi} \left(\frac{\alpha}{m}\right)^{1/2} \quad (43)$$

It can be shown that if the series does not terminate, then ψ increases without limit as x becomes arbitrarily large, and the solution is not physically admissible. Hence, the only characteristic values of the harmonic oscillator are those given by (43). Comparison with (27) shows that the new quantum mechanics gives the same energy levels for the harmonic oscillator as does the old Bohr theory, except for an additive constant which is equivalent to the use of half quantum numbers in (27). Usually it is unimportant whether the extra term $\frac{1}{2} h \nu_0$ is included, but by study of the shift between the electronic spectra of diatomic molecules differing only in being composed of different isotopes, it is possible to decide experimentally between (27) and (43), and the results unequivocally favour the latter.

4. Hydrogen Atom.—The focal point of the old Bohr theory was its success with the hydrogen atom, and one is naturally anxious to know whether these triumphs are reproduced by wave mechanics. It turns out that the Schrödinger theory usually gives exactly the same energy levels for a hydrogenic atom as did that of Bohr. This remarkable coincidence holds even inclusive of the corrections for the motion of the nucleus, and in the first-order Stark effect. Thus, all the standard achievements of the old Bohr theory regarding the Rydberg constant, hydrogen-helium shift, spectroscopic determination of e/m , etc., are reproduced with wave mechanics. When second powers of the electric field are included in the Stark effect, the results are slightly different with wave mechanics, and the experimental results favour the new formula, though observation of the effect of the second-order corrections requires such high field strengths that precision is difficult. The details of the mathematical analysis will not be given here, but a few salient points will be cited. The calculation for hydrogen is unlike the illustrations of the rotator and oscillator given above, inasmuch as there are three degrees of freedom rather than only one. A problem involving more than one co-ordinate is exactly soluble in wave mechanics as a rule only if the variables are separable; i.e., if co-ordinates can be found such that the wave equation admits a solution which can be resolved into products of factors, each of which involves only one co-ordinate. Fortunately such a decomposition is possible for the hydrogen atom. Variables can be separated by using polar co-ordinates, and the wave function then takes the form

$$\psi = A R_{nl}(r) P_l^{m_l}(\cos \theta) e^{im_l \varphi} \quad (44)$$

Here $P_l^{m_l}$ is an associated Legendre function (in which $|m_l|$ is the absolute value of m_l), and R_{nl} is the product of an exponential factor and a polynomial in r (a derivative of the so-called Laguerre polynomial). The constant A is arbitrary, while n, l, m_l are integers. The mathematical problem is very similar to the familiar one of the solution of Laplace's equation in polar co-ordinates, except that the differential equation satisfied by the radial factor is different, no longer admitting a solution in the form of a simple power of r as in the Laplacian case. For the Stark effect, the separation of variables is achieved by using parabolic rather than polar co-ordinates. Both of these types of co-ordinates are special cases of elliptical co-ordinates, and Eisenhart showed generally that if the Schrödinger equation for a single particle admits separation at all, it must be with elliptical co-ordinates.

5. Continuous Spectra.—So far the impression has been given that the characteristic values form a discrete rather than continuous manifold. However, there are certain ranges within which any value of the energy is allowable. The simplest example is furnished by the hydrogen atom. Here, in addition to any of the discrete negative values (21), any positive value of the energy is allowable. The reason for this distinction is the following. The differential equation satisfied by the radial factor of the wave function for the hydrogen atom has two singular points; viz., the origin and the point at infinity. There is always one

solution which is regular at the origin, but it will in general increase without limit at infinity if $E < 0$. Only certain special negative values of E avoid this catastrophe, and these are the characteristic values. When, however, the energy constant E is positive, all solutions vanish at infinity, and so the solution which behaves properly at the origin also necessarily does the same at infinity. Hence any positive value of E is a characteristic value. This remark applies even to nonhydrogenic atoms if the origin of the energy is chosen at ionization. The existence of this continuous manifold of positive energy values is reflected experimentally in the continuous absorption beyond the series limit. In fig. 3 the transitions from a fixed lower state to upper states with larger and larger values of n give rise to lines which crowd closer and closer together. Because there can also be transitions to states in the continuum there is a continuous spectrum beyond the limit corresponding to $n = \infty$.

FIG. 3.—DISCRETE AND CONTINUOUS ENERGY LEVELS OF A HYDROGENIC ATOM

There can also be transitions between two values of the energy in the continuous domain, and it is by this mechanism that the continuous X-ray spectrum is emitted from the anode of an X-ray tube.

6. More General Form of the Wave Equation.—So far, in (35), we have given the form of the wave equation for a conservative system consisting of a single particle and having a definite energy. We need a rule for forming the wave equation in other cases, involving either more than one particle or an indefinite energy, or both. In classical theory a conservative system necessarily has a definite, constant energy, but in quantum mechanics this need not be so, as is discussed below more fully in connection with the Heisenberg uncertainty principle. As a result, it is no longer redundant to say that a conservative system has a definite energy. The more general scheme for forming the wave equation given here also applies to the nonconservative case in which the potential energy V contains the time explicitly.

The procedure is as follows. First of all, the Hamiltonian technique is to be used; i.e., the system is to have associated with it a classical Hamiltonian function $H(q_1, \dots, q_f, p_1, \dots, p_f, t)$, which is a function of the co-ordinates and momenta. We replace p_k by the operator $\frac{h}{2\pi i} \frac{\partial}{\partial q_k}$, and in this fashion we can form a linear differential equation

$$\left[H\left(q_1, \dots, q_f, \frac{h}{2\pi i} \frac{\partial}{\partial q_1}, \dots, \frac{h}{2\pi i} \frac{\partial}{\partial q_f}, t\right) + \frac{h}{2\pi i} \frac{\partial}{\partial t} \right] \Psi = 0 \quad (45)$$

This is the general wave equation. One is led to it primarily by comparison with other forms of quantum mechanics, especially transformation theory, rather than through the De Broglie and Schrödinger interpretation of the Hamiltonian analogy.

In case the system is conservative, so that t does not enter explicitly, (45) will admit a solution of the form

$$\Psi = e^{-2\pi i E_m t / h} \psi_m(q_1, \dots, q_f) \quad (46)$$

where ψ_m is independent of t and satisfies the equation

$$\left[H\left(q_1, \dots, q_f, \frac{h}{2\pi i} \frac{\partial}{\partial q_1}, \dots, \frac{h}{2\pi i} \frac{\partial}{\partial q_f}\right) - E_m \right] \psi_m = 0 \quad (47)$$

However, (46) does not represent the most general solution of (45) for a conservative system, which is

$$\Psi = \sum_m c_m e^{-2\pi i E_m t / h} \psi_m \quad (48)$$

where the summation is over all the characteristic values E_m and where the c_m are arbitrary constants. The expression (46) presupposes that the energy has a definite value, whereas (48) does not involve this restriction.

Equation (47) reduces to (35) for a one-particle system, where the classical Hamiltonian function is $(p_x^2 + p_y^2 + p_z^2)/2m + V$.

To include the correction for the motion of the nucleus, it is necessary to add to this Hamiltonian function an extra term $(p_x^2 + p_y^2 + p_z^2)/2M$, where M and p_x, p_y, p_z are respectively the mass and components of momentum of the nucleus. It is, of course, then necessary to use the general equation (47) rather than (35). It can be shown that the variables can be separated by changing them from $x, y, z, \xi, \eta, \zeta$ to $X, Y, Z, r, \theta, \varphi$ where X, Y, Z are the Cartesian co-ordinates of the centre of gravity, and r, θ, φ are polar co-ordinates with origin at the nucleus. The solution of the wave equation takes a form similar to (44) except that there is an extra factor $e^{ik_x X} e^{ik_y Y} e^{ik_z Z}$ which allows for the motion of the centre of gravity of the system, and in which k_1, k_2, k_3 are arbitrary constants. The differential equation satisfied by the "internal" part of the wave function (i.e., the part depending on r, θ, φ) can be shown to be the same as for the one-body problem, in which the nuclear motion is disregarded, except that the reduced mass (17) appears in place of the electronic mass m . The total energy—i.e., the characteristic value of (47)—is the sum of the internal energy given by (21) and an extra term $(k_1^2 + k_2^2 + k_3^2)h^2/8\pi^2(m + M)$ which represents the translational kinetic energy of the centre of gravity of the system. In the discussion of the Bohr theory above, this translational energy was omitted, but its inclusion in the Bohr frequency condition introduces a correction to the frequency which is essentially the quantum analogue of the classical Doppler effect, and yields results substantially equivalent to the latter.

An important property of (47) is that its solutions can be shown to be orthogonal, provided the operator is of the so-called self-adjoint type. This condition is one which can practically always be met. If, in addition, the arbitrary proportionality constants in the wave function are so chosen that they are normalized to unity, one has the relation

$$\int \psi_l^* \psi_m d\tau = \delta_{lm}^* \quad (49)$$

where $d\tau$ is a volume element embracing the co-ordinate space of all the particles (of dimensionality $3n$ if there are n particles), and where the integration is over all the co-ordinates. The expression δ_{lm}^* is the usual Kronecker delta, and has the meaning that $\delta_{mm}^* = 1$ and that $\delta_{lm}^* = 0$ ($l \neq m$). The asterisk is used here and elsewhere to denote the complex conjugate. It is necessary to distinguish between ψ_m and its conjugate ψ_m^* , because the solutions of the Schrödinger wave equation are not necessarily real. In (49) the case $l \neq m$ expresses the orthogonality, and $l = m$ embodies the normalization.

B. MATRIX FORM OF QUANTUM MECHANICS

A few months prior to Schrödinger's discovery of wave mechanics, another, superficially very different approach to quantum mechanics was developed by Born and Heisenberg. The impetus to this other approach was Born's repeated emphasis to his colleagues at Göttingen that the reason the old quantum theory was then (1925) failing was that it sought to use the same kinematical concepts of space and time within the atom as in ordinary measurable large-scale events. After all, the concepts of space and time have a meaning only when we tell how they can be measured, and obviously at atomic distances we cannot use ordinary measuring rods or clocks. Guided by this philosophy based on the so-called operational viewpoint, Heisenberg discovered his matrix mechanics. He did not originally recognize it as a matrix formulation—Born was the first to see that the equations were best interpreted in the language of matrices.

The basic idea of the matrix mechanics is that the co-ordinates and momenta associated with the electrons in the atom are to be treated as matrices rather than as quantities having a definite numerical value. A matrix is an array of the form

$$a = \begin{Bmatrix} a(11) & a(12) & a(13) & \dots \\ a(21) & a(22) & a(23) & \dots \\ a(31) & a(32) & a(33) & \dots \\ \vdots & \vdots & \vdots & \ddots \end{Bmatrix} \quad a(nn)$$

The matrices involved in quantum mechanics are infinite; i.e., have an infinite number of rows and columns.

The Heisenberg matrix elements are quantities which are intimately connected with the concept of the transition probability in the old quantum theory, and alternatively with Fourier coefficients in classical mechanics. For simplicity consider a system with only one degree of freedom. Then the matrix index can be identified with the quantum number, and a matrix element $a(lm)$ is correlated with a transition between states of quantum numbers l and m . The exact matrix expression replacing (31) is

$$A_{l \rightarrow m} = (4e^2/3hc^3) (2\pi)^4 v(lm)^2 [|x(lm)|^2 + |y(lm)|^2 + |z(lm)|^2] \quad (50)$$

Here $x(lm)$ refers to an element of the x co-ordinate matrix, etc., and is the quantum analogue of the Fourier coefficient x_{l-m} involved in the rough formula (31) arrived at by means of the correspondence principle. As presented here, and as Heisenberg reasoned historically, (50) is obtained by analogy with classical theory, but it should be mentioned that (50) can also be derived independently from the Dirac radiation theory, which applies quantum mechanics to the degrees of freedom of the ether. By means of (50) the intensity of a line can be calculated if the Heisenberg matrices are known.

In order to compute the matrix elements needed for use in (50), it is necessary to transcribe atomic mechanics into the mysterious matrix language, and for this a matrix algebra and calculus are necessary. The sum of two matrices is formed by adding corresponding elements, so that $(a+b)(lm) = a(lm) + b(lm)$. Matrices are multiplied in the same way as determinants; i.e.,

$$(ab)(lm) = \sum_n a(ln)b(nm) \quad (51)$$

There is, however, the difference that whereas a determinant has a numerical value, a numerical meaning is attached only to the individual entries of a matrix and not to its entirety. This loss of numerical value corresponds to the abandonment of ordinary kinematical relationships within the atom. The multiplication is in general noncommutative; i.e., $(ab)(lm) \neq (ba)(lm)$ or more symbolically $ab \neq ba$, if boldface type is used to designate the entire matrix rather than a single entry.

By repeated additions and multiplications it is possible to construct functions of matrices which are in turn matrices, and thus develop a matrix algebra. In order to transcribe atomic mechanics into the mysterious matrix language, it is necessary to have some sort of rule for constructing the derivative of one matrix with respect to another. A consistent mathematical framework is obtained if one defines the derivatives of a function $f(q_1, \dots, q_l, p_1, \dots, p_l)$ in the following way:

$$\frac{\partial f}{\partial p_k} = \frac{2\pi i}{h} (f q_k - q_k f), \quad \frac{\partial f}{\partial q_k} = -\frac{2\pi i}{h} (f p_k - p_k f) \quad (52)$$

The special cases $f = p_j$ or q_j yield the so-called quantum conditions

$$\begin{aligned} p_k q_k - q_k p_k &= (h/2\pi i) 1 & p_k q_j - q_j p_k &= 0 & (k \neq j) \\ p_k p_j - p_j p_k &= 0 & q_k q_j - q_j q_k &= 0 \end{aligned} \quad (53)$$

A diagonal matrix is one which has vanishing entries except down the principal diagonal—i.e., $a(lm) = 0$, $l \neq m$ —while a unit matrix has the additional property $1(l) = 1$. A diagonal matrix is the quantum analogue of a Fourier series which contains nothing but a single constant term. Hence, in a conservative system with a definite energy, the energy matrix must be a diagonal one.

It should be stated again that the Heisenberg matrices are infinite arrays in the sense that they involve an infinite number of rows of columns. Namely, each index (number of row or column) is correlated with a stationary state, and there is an infinite number of such states. Furthermore, in connection with fig. 3 we have seen that often the permitted stationary states form a continuous rather than discrete manifold. In the continuous region it is necessary to introduce the rather recondite concept of a matrix with continuously varying indices, so that it cannot then even be tabulated in terms of rows and columns. When there is a continuum, the summation in (51) must be replaced by an integration. Similarly, in the expansion (48) the summations are to be construed as including integrations over the continua when these are present.

1. Relation of Matrix and Wave Theories.—It is possible to work out the energy levels of the harmonic oscillator, rotator, hydrogen atom, etc., by means of pure matrix theory, and the results are always the same as those obtained with wave mechanics. One immediately suspects that the two approaches are interrelated. This is indeed the case. If the Schrödinger wave functions are known, the Heisenberg matrix elements can be computed by a straightforward integration. Suppose that we desire the matrix elements of a function $f(q_1, \dots, q_l, p_1, \dots, p_l)$ of the co-ordinates and momenta. Then the appropriate formula is

$$f(lm) = \int \psi_m^* f(q_1, \dots, q_l, \frac{h}{2\pi i} \frac{\partial}{\partial q_1}, \dots, \frac{h}{2\pi i} \frac{\partial}{\partial q_l}) \psi_l d\tau \quad (54)$$

where the integrand contains an operator f formed by replacing each p_k by $\frac{h}{2\pi i} \frac{\partial}{\partial q_k}$. We shall not attempt to prove (54) but shall note one or two simple consequences. In the first place, the quantum conditions (53) are satisfied. For instance, if $f = p_k q_k - q_k p_k$, then

$$f\psi_m = \frac{h}{2\pi i} \left[\frac{\partial}{\partial q_k} (q_k \psi_m) - q_k \frac{\partial \psi_m}{\partial q_k} \right] = \frac{h}{2\pi i} \psi_m$$

and except for a factor $h/2\pi i$, the integral (54) becomes identical with (49), so that we have $f(lm) = (h/2\pi i) \delta_{lm}$. This result agrees with the first relation of (53), since the elements of a unit matrix are equivalent to a Kronecker delta. The remaining relations of (53) are obviously satisfied. The third relation, for instance, follows since $\partial^2 \psi / \partial q_k \partial q_k = \partial^2 \psi / \partial q_k \partial q_k$.

Satisfaction of the wave equation (47) for a conservative system with definite energy is tantamount to making the energy a diagonal matrix. To see this we note that by (47) the operator H is equivalent to multiplication by a constant E_m . Hence, if f in (54) is taken to be the Hamiltonian operator H , the integral differs from (49) merely by a constant factor and so has the value $E_m \delta_{lm}$.

If one is wedded to the extreme matrix viewpoint, one regards the wave functions merely as mathematical auxiliaries used to compute the Heisenberg matrix elements by means of the "matrix computing machine" (54). Such a viewpoint is undoubtedly too one-sided, and is offensive to physicists who take comfort from the parallelism of wave mechanics to classical mathematical physics, and to optics, in particular.

2. Intensities and Polarizations of Spectral Lines.—By combining (54) (as applied to $f = x, y, z$) with (50), it is possible to compute the intensities of spectral lines. Furthermore, by examination of the relative magnitudes and phases of the corresponding x, y , and z components involved in (50), predictions can also be made regarding the polarization behaviour. In this fashion, for example, the intensities in the various components in the Stark effect for hydrogen can be calculated. Also, and even more important, it is possible to derive the various so-called "selection rules," which forbid certain quantum numbers changing except by a specified number of units. It can be demonstrated, for instance, that the quantum number for a harmonic oscillator cannot change by more than one unit. With the restriction $n'' - n' = \pm 1$, the quantum-mechanical frequency ν obtained by substituting (43) in (13) becomes identical with the classical frequency ν_0 . Without the restriction, ν could be any multiple of ν_0 , a highly unreasonable situation since classically overtones are always absent for a simple harmonic system.

A particularly important case of the selection principle is that for the so-called azimuthal quantum number l , which is involved in the relativistic hydrogen atom and especially in Newtonian nonhydrogenic atoms with one valence electron. By means of (54) it can be proved that l cannot change except by one unit. The quantum number l plays a vital role in interpreting the spectra of alkali atoms. (See SPECTROSCOPY.) An energy level is classified of the s, p, d, f character according as $l = 0, 1, 2, 3$. The selection principle $l' - l'' = \pm 1$ materially limits the "combinations" of the terms; i.e., the possible transitions between the different energy states. The predictions are strikingly confirmed by experiment.

C. STATISTICAL SIGNIFICANCE OF QUANTUM MECHANICS

1. Interpretation of the Wave Function.—We have not as yet given sufficient emphasis to the physical meaning of the solution of the Schrödinger wave equation, as distinct from its relation to the matrix formalism. The wave function satisfying the general equation (45) has an important physical interpretation. The square of its modulus is proportional to what may be called a statistical charge density. Let us consider first a system with only one particle. Then the probability that the particle will be in the volume element $dx dy dz$ at time t may be taken to be

$$|\Psi|^2 dx dy dz \quad (55)$$

provided the total probability is normalized to unity; i.e.,

$$\iiint |\Psi|^2 dx dy dz = 1 \quad (56)$$

This scheme of interpretation is a consistent one, as it can be shown that it is a consequence of the differential equation (45) that the integral on the left-hand side of (56) is independent of time. Otherwise the normalization condition (56) could not be imposed. Similarly, when there are n particles, $|\Psi|^2$ determines the probability in a $3n$ dimensional space whose volume element $d\tau$ is dx_1, \dots, dz_n .

It is to be emphasized that the density given by (55) is inherently statistical in character. We do not say that the particle is in the element $dx dy dz$ at time t , but merely that there is a certain probability of the particle being there. In the particular case of a conservative system in a definite stationary state, the relation $|\Psi|^2 = |\psi_m|^2$ is satisfied by virtue of (46), and then the probability becomes independent of time. The places where $|\Psi|$ or $|\psi_m|$ is large are those where the particle is likely to be located, but it is never possible to say when it is there. The situation may be compared to the information obtainable from the time exposure of a firefly on a dark night. Where the photographic plate reveals the most brightness is where the firefly has spent most of the time, but one cannot infer just when the insect was at a particular spot. Similarly in quantum mechanics, the information about particles is inherently restricted because of its statistical nature.

When quantum mechanics was first discovered, there was considerable controversy as to whether it was necessarily statistical in character. For a while many physicists maintained that a deterministic picture was possible, in which the electron was considered to be a fluidlike affair whose density distribution is governed by (55). It is now, however, generally conceded that such attempts are untenable and involve the same fallacy as reasoning from the time exposure of the firefly that the latter is a luminous fluid rather than a discrete insect. It should be regarded as an advantage rather than a drawback that quantum mechanics must be interpreted statistically. When atomic experiments are analyzed from the "operational" viewpoint, it is found that the measurements always involve statistical features inasmuch as some of the parameters are distributed over a range of values and are not determined with complete precision. It is not the co-ordinates alone which must be statistically interpreted, but also various other dynamical quantities, such as energy and momentum.

2. Probability Distribution in Momentum Space.—Again confining attention to one particle, it is possible, for instance, to inquire concerning the probability that its components of momentum fall within a certain range at time t . The symmetrical roles of co-ordinates and momenta in the Hamiltonian technique suggest that there is a function χ such that

$$|\chi(p_x, p_y, p_z, t)|^2 dp_x dp_y dp_z \quad (57)$$

determines the probability that the momenta are in the element $dp_x dp_y dp_z$ at time t . There is indeed such a function, and the relation between the two functions Ψ, χ is similar to that between a function and its Fourier transform. Namely, it can be shown that

$$\Psi = h^{-3/2} \iiint \chi(p_x, p_y, p_z, t) e^{2\pi i(p_x x + p_y y + p_z z)/h} dp_x dp_y dp_z \quad (58)$$

$$\chi = h^{-3/2} \iiint \Psi(x, y, z, t) e^{-2\pi i(p_x x + p_y y + p_z z)/h} dx dy dz \quad (59)$$

Equation (58) has intuitively a very reasonable form, as it is natural to regard any disturbance as being built up of a superposition of De Broglie waves, each of the structure $e^{2\pi i p x/h}$ in one dimension or $e^{2\pi i(p_x x + p_y y + p_z z)/h}$ in three. In any principle of superposition in physics, the square of the amplitude governs the intensity, and so it is natural to assume that $|\chi|^2$ gives the probability. It can be shown from the mathematical theory of Fourier transforms (Plancherel's theorem) that

$$\iiint |\Psi|^2 dx dy dz = \iiint |\chi|^2 dp_x dp_y dp_z \quad (60)$$

If (60) were not satisfied, the physical interpretation given Ψ, χ would lack consistency, for it is necessary that the total probability for either co-ordinate or momentum distribution be unity; or in other words, the normalization (49) in co-ordinate space must imply a corresponding normalization in momentum space. Another relation which can be established, and which shows the intimate relation between momentum and the operator $\frac{h}{2\pi i} \frac{\partial}{\partial x}$, is

$$\iiint p_x^n |\chi|^2 dp_x dp_y dp_z = \iiint \Psi^* \left(\frac{h}{2\pi i} \frac{\partial}{\partial x} \right)^n \Psi dx dy dz \quad (61)$$

where n is an integer. Also there is a symmetrical relation

$$\iiint x^n |\Psi|^2 dx dy dz = \iiint \chi^* \left(-\frac{h}{2\pi i} \frac{\partial}{\partial p_x} \right)^n \chi dp_x dp_y dp_z \quad (62)$$

Clearly (62) and (61) give respectively the mean value of the n th power of the x -component of displacement and of momentum.

3. Interference of Probability Amplitudes.—In ordinary probability theory, probabilities are compounded in accordance with the law

$$P(b) = \int P(b, a) P(a) da \quad (63)$$

where $P(a)$ is the probability of occurrence of a , and $P(b, a)$ is the probability of occurrence of b when a is given. On the other hand, since $|\Psi|^2$ or $|\chi|^2$ is the density in position or momentum space, the functions involved in the compounding relation (equation 58) are the square roots of probabilities and are spoken of as being probability amplitudes. The function $e^{2\pi i(p_x x + p_y y + p_z z)/h}$ is essentially a De Broglie wave and is called the probability amplitude connecting co-ordinates and momenta. The fact that in quantum mechanics there exists a compounding relation analogous to (63) with $P^{1/2}$ rather than P is sometimes called the phenomenon that involves the interference of probability amplitudes. Although no logical inconsistencies are found to be involved, still this somewhat curious way of associating probabilities leads to many paradoxes which look rather strange from the standpoint of large-scale statistical mechanics. There is a certain amount of parallelism to the unintelligibility of interference phenomena in optics, wherein amplitudes rather than intensities are added, to a person who has been versed only in geometrical optics, ray tracing, and perhaps the corpuscular theory of light. It is now well recognized that radiation has both corpuscular and undulatory aspects. The former, for instance, stands out clearly in the photoelectric effect. As emphasized in Bohr's principle of complementarity, the two aspects are not contradictory but instead play complementary roles. So also, matter has both corpuscular and undulatory features. The type of compounding involved in (58) implies use of the wave amplitude in much the same way as in optics. It is well known that interference phenomena in the latter must be treated by superposing wave amplitudes rather than intensities or the number of corpuscular light quanta.

D. TRANSFORMATION THEORY

1. General.—The general interpretation of quantum mechanics as essentially a theory of probability amplitudes has been developed particularly by Jordan and by Dirac. The details of this so-called transformation theory are much too intricate and abstract to be treated here, but their formulation of quantum mechanics has elegance, generality and a unifying influence on the

interpretation of the various other viewpoints. The Schrödinger wave equation, from the standpoint of transformation theory, may be regarded as an equation for finding the probability amplitude for distribution-in-position when the energy is known. One might ask for the probability amplitude for the distribution of other functions than positional co-ordinates—for instance, momenta—and the known quantity might not necessarily be the energy, as certain experiments correspond to fixation of other quantities than the energy. Such more general problems can be solved by means of transformation theory.

2. Uncertainty Principle.—It is to be noticed that in (55) or (57) expressions have been given for the probability of the particle being in an element of volume $dx dy dz$ of position space, or in an element of momentum space, but that there is no probability function for a concurrent occurrence of given values of position and momentum associated with a volume element $dx dy dz dp_x dp_y dp_z$. This fact takes us to the heart of the Heisenberg uncertainty principle. The latter limits the accuracy with which it is possible to specify simultaneously the values of a co-ordinate and its canonically conjugate momentum. If Δp_x and Δx be the limits of precision within which p_x and x can simultaneously be determined, there exists the inequality

$$\Delta x \Delta p_x \geq h/4\pi \quad (64)$$

For illustrations of this concept, see UNCERTAINTY PRINCIPLE; thus it is meaningless to talk about the probability of a simultaneous occurrence of a given value of a co-ordinate and its conjugate momentum, for by (64) there is infinite uncertainty in a momentum if the position is known with complete precision, or vice versa.

The uncertainty principle should not be regarded as an additional hypothesis artificially injected into quantum mechanics. Instead, it is something which can be proved as a consequence of the latter, along the following lines. By proper choice of the origin for position and velocity, the mean position and velocity can be made zero; in other words, $I_{x1}^{(1)} = I_{x2}^{(1)} = 0$, where $I_{x1}^{(n)}$, $I_{x2}^{(n)}$ denote respectively the integrals (61) and (62). The uncertainty in position and momenta can then be regarded as measured by the root mean square displacement and momentum, so that we can take $\Delta p_x^2 = I_{p1}^{(2)}$, $\Delta x^2 = I_{x2}^{(2)}$ provided Ψ is normalized in accordance with (56). Now it can be shown by pure mathematics, largely by the aid of the so-called Schwarz inequality, that any function Ψ normalized in accordance with (56) and satisfying the requirements of continuity, etc. expected of a physically admissible wave function satisfies the identity $I_{x1}^{(2)} I_{p2}^{(2)} \geq (h/4\pi)^2$. The uncertainty principle is hence proved for the type of system under consideration. The equality sign in (64) corresponds to the minimum possible value of the product of the two errors, and this is achieved only when the probability functions have a Gaussian distribution.

It can be shown that the time is canonically conjugate to the energy. Hence, if we make an experiment whose span in time is limited, as is always the case, the energy cannot be known with complete precision, and so the appropriate wave function is (48), in which there is a dispersion of energy values, rather than (46), in which it is supposed that the energy is completely determinate. Wave functions of the general form (48), in which a number of stationary states are superposed and thus co-exist, are sometimes spoken of as "wave packets." It is through the construction of the latter that classical and quantum theories merge when the amount of action is large.

V. ELECTRON SPIN

A very important development practically concomitant with the advent of the true quantum mechanics was the discovery of electron spin. The basic idea of the latter is that the electron has an extra degree of freedom which may be likened to the spin of a top about an axis. Or, if the electron moving about the nucleus is compared to the earth in the solar system, then there is an obvious analogy of the spin of the electron to the diurnal rotation of the earth about its own axis. The important features of the spinning electron were first presented by two young Dutch physi-

cists, George E. Uhlenbeck and Samuel A. Goudsmit, in 1925, although some of the earlier literature did contain suggestions of a rotating electron in rather different connections.

The various dilemmas of spectroscopic theory and magnetism which are resolved by the introduction of electron spin are many. One of them is the existence of multiplets in molecular spectra. The simplest and most familiar example of a multiplet is provided by the two components of the D lines of sodium, which arise because the energy level of the upper state is double; *i.e.*, consists really of two stationary states. A single level, however, is obtained if the ordinary theory of a point electron is used. It is hence necessary to introduce a fourth quantum number, whose values subdivide the energy levels more than if only the quantum numbers associated with the external degrees of freedom of the electron were introduced.

If an electron model without spin is used, then there are three quantum numbers per electron. If the force field is dominantly central, as is usually the case even in nonhydrogenic atoms, then these three can be interpreted as the principal quantum number n , the azimuthal quantum number l , and the "magnetic" or "equatorial" quantum number m_l . The range of values of l is 0, ..., $n-1$, and that of m_l is $-l, \dots, +l$. The azimuthal quantum number l has the physical significance of specifying the angular momentum of the electron, in multiples of $h/2\pi$, while m_l fixes the component in a particular direction. The mathematical significance in terms of the indices of tesseral harmonics involved in the wave function is that revealed in equation (44).

1. Pauli Exclusion Principle.—Wolfgang Pauli proposed that besides n, l, m_l there be a fourth quantum number, or index m_s , which can take on the values $\pm \frac{1}{2}$. He then (1925) introduced his famous exclusion principle, for which he was awarded the Nobel prize in 1945. This principle states that no two electrons can have all four quantum numbers n, l, m_l, m_s the same. From this, the properties of the chemists' periodic table flow out automatically, including the existence of the "long" periods containing the iron, platinum and palladium groups, and of 14 rare earths. For instance, the choice $n=1$ for the principal quantum number corresponds to the first or hydrogen-helium period, which has two elements, and $n=2$ to the second or lithium-neon period. Namely, if $n=1$, we can have $l=0, m_l=0, m_s=\pm \frac{1}{2}$, two possibilities in all, whereas if $n=2$, we can have $l=0, m_l=0, m_s=\pm \frac{1}{2}$ and also $l=1, m_l=1, m_s=\pm \frac{1}{2}; l=1, m_l=0, m_s=\pm \frac{1}{2}; l=1, m_l=-1, m_s=\pm \frac{1}{2}$ giving eight possibilities all told. In this general fashion the numbers of elements in the different rows of the periodic table are deduced by a simple enumerative process.

When Pauli published his celebrated paper in 1925, the significance of the fourth quantum number was a complete mystery. The great contribution of the theory of Uhlenbeck and Goudsmit, which appeared less than a year later, was to show how naturally the spinning electron accounts for the Pauli formalism. The two choices $m_s = \pm \frac{1}{2}$ are interpreted as determining the two possible orientations of the spin angular momentum relative to the axis of quantization. In order that there be two choices, and no more, it is necessary to postulate that the electron has a "half quantum" $\frac{1}{2}(h/2\pi)$ of spin angular momentum.

2. Interpretation of the Exclusion Principle in Terms of Antisymmetric Wave Functions.—The spin hypothesis of Uhlenbeck and Goudsmit furnished an explanation of the fourth quantum number. It did not, however, give any indication of why it is that no two electrons have all four quantum numbers the same. Heisenberg was the first to point out that the Pauli exclusion principle has a rudimentary interpretation in terms of the symmetry properties of wave functions. When one solves the wave equation for a system of several like particles, their identity introduces special properties of symmetry, and permits classification of the solution according to symmetry characteristics, the precise codification of which involves complicated group theory. For the very simple special case of only two identical particles, for instance, the solutions are either symmetric or antisymmetric, as regards interchange of the corresponding co-ordinates of the two particles. In other words, the wave function

is either invariant or reverses sign when the electrons are permuted. When there are more than two electrons, there are many types of symmetry intermediate between the symmetric and antisymmetric cases, which represent two extremes but which still have a meaning. Furthermore, the antisymmetric solution can never be constructed when the electrons are in identical states (*i.e.*, have all four quantum numbers the same) for then the wave function would have to reverse sign as a result of an operation which does not change the arguments, an apparent impossibility. Hence, the Pauli principle is an automatic consequence of the formalism of quantum mechanics if it is postulated that only those solutions of the Schrödinger equation which are antisymmetric under permutation of the electron co-ordinates are physically realizable. In other words, nature somehow has a penchant for antisymmetric wave functions. In this connection it is to be understood that all four co-ordinates are to be permuted; *i.e.*, the spin co-ordinate as well as the three ordinary orbital ones x, y, z . The spin co-ordinate, unlike the variables x, y, z , which are continuous, assumes only the two values which correspond to the two possible orientations of the spin angular momentum relative to the axis of quantization. The wave function, on the other hand, need not be antisymmetric with respect to permutation of the orbital co-ordinates alone. In fact, no rigorous delineation of symmetry types under purely orbital permutation is possible, although it can be shown that symmetry characteristics associated with the orbital part of the problem determine the multiplicity of a spectral term; *i.e.*, whether it is a singlet, doublet, triplet, etc. The purely orbital forms of the wave equation given in (35) or (45) do not take cognizance of the spin. Inclusion of the latter introduces certain small magnetic interaction terms involving spin operators in the Hamiltonian function, and requires that the arguments of the wave function include spin variables as well as the ordinary orbital co-ordinates q_1, \dots, q_f .

3. Electron Spin and Magnetism.—Electron spin plays a leading role in the theoretical interpretation of magnetic phenomena. A fuller description will be found in the article on **MAGNETISM**; only two points will be mentioned here. One is that ferromagnetism arises almost entirely from spin rather than from orbital magnetic moment, for in the solid state the crystalline electric fields usually quench the orbital contributions to the magnetic moment. The other is that in the Uhlenbeck-Goudsmit model of electron spin the ratio of magnetic moment to angular momentum is taken to be $-e/mc$, whereas the classical value of the ratio which applies to the orbit is $-e/2mc$. In other words, the so-called gyromagnetic ratio has an anomalous factor 2 when applied to the spin. This anomaly is confirmed not only by measurements on the gyromagnetic effect (rotation of a body by magnetization, or magnetization by rotation), but also by those on the anomalous Zeeman effect. In the latter the so-called Landé g -factor expresses the fact that part of the contribution to the magnetic moment is of the normal orbital type, and part of the anomalous spin variety.

VI. DIRAC ELECTRON

1. General.—In the Uhlenbeck-Goudsmit theory, the half quantum of spin angular momentum and the anomalous factor 2 in the gyromagnetic ratio are introduced in a purely *ad hoc* fashion. Another approach, which avoids this arbitrariness, was developed by Dirac in 1928. In the original Schrödinger theory without spin, the behaviour of an electron was described by a single second-order differential equation. The spin properties assumed by Uhlenbeck and Goudsmit involved two different possible settings of space-quantized spin angular momentum, and were interpreted by means of the matrix theory. Pauli, however, soon showed how the Schrödinger wave theory could be generalized to include the spin, by introducing two wave functions, ψ_1, ψ_2 , which satisfy two simultaneous second-order differential equations. Dirac had the revolutionary idea that the electron be described by four wave functions, $\psi_1, \psi_2, \psi_3, \psi_4$, which satisfy four simultaneous first-order differential equations. If the electron is subject to an electrostatic potential $\varphi(x, y, z)$ and vector potential A , these equations are as follows:

$$\begin{aligned} (\not{p}_0 + mc)\psi_1 + (\not{p}_1 - i\not{p}_2)\psi_4 + \not{p}_3\psi_3 &= 0 \\ (\not{p}_0 + mc)\psi_2 + (\not{p}_1 + i\not{p}_2)\psi_3 - \not{p}_3\psi_4 &= 0 \\ (\not{p}_0 - mc)\psi_3 + (\not{p}_1 - i\not{p}_2)\psi_2 + \not{p}_3\psi_1 &= 0 \\ (\not{p}_0 - mc)\psi_4 + (\not{p}_1 + i\not{p}_2)\psi_1 - \not{p}_3\psi_2 &= 0 \end{aligned} \quad (65)$$

where

$$\begin{aligned} \not{p}_0 &= \frac{\hbar}{2\pi ic} \frac{\partial}{\partial t} + \frac{e}{c} \varphi & \not{p}_1 &= \frac{\hbar}{2\pi i} \frac{\partial}{\partial x} + \frac{e}{c} A_x \\ \not{p}_2 &= \frac{\hbar}{2\pi i} \frac{\partial}{\partial y} + \frac{e}{c} A_y & \not{p}_3 &= \frac{\hbar}{2\pi i} \frac{\partial}{\partial z} + \frac{e}{c} A_z \end{aligned}$$

When first viewed, these equations certainly look arbitrary and artificial. Space will not permit description of how, to the first approximation in the dimensionless constant $(2\pi e^2/\hbar c)^2$, they are equivalent to the more conventional theory based on second-order differential equations. It was this equivalence that first led Dirac to hit upon the equations of the structure (65). If the solutions are normalized to unity in the sense that

$$\iiint [|\psi_1|^2 + |\psi_2|^2 + |\psi_3|^2 + |\psi_4|^2] dx dy dz = 1$$

then $(|\psi_1|^2 + |\psi_3|^2) dx dy dz$ and $(|\psi_2|^2 + |\psi_4|^2) dx dy dz$ are respectively the probabilities that the electron be in the volume element $dx dy dz$ with spin parallel or antiparallel to the axis of quantization. It can further be shown that the simultaneous equations (65) have the proper invariance under a Lorentz transformation, so that the requirements of the special theory of relativity are satisfied. This is not true of the simple Schrödinger equation (35), which is essentially Newtonian in character. The relativistic transformation properties of $\psi_1, \psi_2, \psi_3, \psi_4$ are those appropriate to a pair of spinors, each of which has two components. This result is rather surprising, as one's first conjecture would be that the ψ functions would transform like the components of a four-vector.

All the properties of electron spin, including the proper amount of angular momentum, relativistic fine structure and even the gyromagnetic ratio, flow out of the Dirac formalism in an almost miraculous fashion suggestive of a magician's extraction of rabbits from a silk hat. Of course, some mathematical calculation, omitted here, is required to demonstrate that these various properties are indeed implied in (65), but it should be emphasized particularly that when (65) is used, no additional postulates are necessary as in the original theory of Uhlenbeck and Goudsmit. Thus (65) can be regarded as the basis of a relativistic electron, with spin as a by-product. In fact, the discovery of (65) and related methodology must be regarded as one of the most brilliant achievements in the history of mathematical physics.

When the Dirac equations (65) are used, the expressions for the energy levels of a hydrogenic atom have exactly the same form (24) as in the original relativistic Bohr-Sommerfeld theory. This identity of results must be regarded as one of the strangest coincidences in all of physics. In other words, the new quantum mechanics with spin is equivalent to the old theory without spin. Unless the spin is included in some form, either explicitly through the Uhlenbeck-Goudsmit model (which, however, is reliable only to the approximation [26]) or implicitly through the more refined Dirac equations, relativistic wave mechanics gives results different from (24) and not in accord with experiment. There is an important difference between the new and old interpretations of (24). The integer k no longer has the significance of being the azimuthal quantum number, as in the old quantum theory, but rather is equal to $j + \frac{1}{2}$, where j is the so-called inner quantum number which takes on half-integral values. The selection principles allow transitions in which the inner quantum number is unaltered as well as those in which it changes by ± 1 , whereas only the ± 1 changes are allowed for the azimuthal quantum number. Hence, even though the energy levels are exactly the same, more spectral lines are allowed in the new than in the old interpretation of the relativistic fine structure. The extra components are confirmed experimentally, although the resolution is usually inadequate to detect them except as satellites of other lines.

Another success of the Dirac model is that it yields the so-called

Klein-Nishina formula for the scattering of X-rays, which, unlike previous expressions, agrees well with experiment.

2. Negative Energy States and the Positron.—To this point, only the triumphs of the Dirac theory have been stressed. Some of its difficulties should also be mentioned. One is that it is uncertain how the relativistic theory should be extended to include the interaction between electrons found in nonhydrogenic atoms. A more serious trouble is the existence of the so-called negative energy states. It is convenient and hence customary in relativity to include, as will be done henceforth, the so-called rest energy mc^2 of the electron in the total energy. This inclusion is equivalent to omitting the term -1 from the brace in (24), and with this modification the energy levels given by (24) are all positive. The dividing line between the discrete and continuous levels in fig. 3 then comes at $E = mc^2$. The equivalence of energy levels in the old and new theories mentioned above applies only as long as attention is confined to states of positive energy. The old quantum theory gave no negative states. However, it can be shown that with the Dirac equations (65) there is a continuum of states of negative energy, filling the entire range of energies below $-mc^2$. The rest energy mc^2 is enormously greater than the binding energy of the hydrogen atom, represented by the span of the discrete levels in fig. 3. The interval between the lowest positive state and the highest negative one is thus very approximately $2mc^2$, or about 1,000,000 ev. To show even the highest negative energy level, it would be necessary to extend fig. 3 about two miles below the bottom of the page, the intervening interval being void, and from there down to minus infinity the figure should be shaded to indicate a continuum. (By contrast it should be noted that the relativity fine structure, first revealed by the second member of the expansion [26] of [24], also cannot be shown in fig. 3, but for a different reason, as on the scale of fig. 3 the splitting would amount to only about a millionth of an inch.)

The states of negative energy are obviously supernumerary and superfluous if viewed in a conventional fashion, and to get a theory that has a meaning, they must somehow be stricken off the books. Dirac suggested that the negative states are to be regarded as filled, each having the one electron allowed by the Pauli exclusion principle. This idea, of course, would not work with conventional Boltzmann statistics without the exclusion principle, as then there would be an overwhelming probability that the electrons be in states of negatively infinite energy. As there is a nondenumerable infinity of negative energy levels, there would be an infinite number of electrons housed in such states, even with the limitations imposed by the Pauli rule. Since the electron has a negative charge, there would hence be an infinite negative charge density. Dirac proposed that the charge is not to be counted in computing the charge density to be used in such relationships as the Poisson law.

According to this apparently fantastic conception, if an electron were somehow taken from one of the normally filled states of negative energy and placed in one of the conventional ones of positive energy, not only would an electron be created, but also a particle of equal mass but positive charge, now called the positron. Namely, a deficit in the full complement of negative charge, carried, so to speak, at zero on the books, is equivalent to a corresponding surplus of positive charge. (Dirac suggested originally that the shortage might correspond to the proton, but this idea is now considered untenable as, for one thing, no explanation is given of the diversity of mass between electron and proton.) Fantasy turned to evidence when Carl D. Anderson obtained cloud chamber photographs showing the existence of positrons; *i.e.*, particles equal to the electron in mass but positively charged. They should not be confused with protons, which are almost 2,000 times heavier. Unlike the protons, which are stable, positrons are extremely short-lived, as there is always the possibility that an electron will be captured out of a state of positive energy and fill the gap in the negative one. Raising of an electron from a negative to a positive level is equivalent to the creation of an electron and a positron, or in other language to pair production. The minimum energy involved in such a transition is very approximately $2mc^2$. Hence, the absorption of gamma rays can give rise to pair pro-

duction if, and only if, their frequency exceeds $2mc^2/h$. In the experimental confirmation of this phenomenon, an apparent difficulty of the Dirac theory is turned into a triumph.

A positron and electron which are near each other move about their common centre of gravity in much the same fashion as do the electron and proton in the hydrogen atom but without the disproportionality in mass between the two constituents. The quasi-atom thus formed is called positronium and is highly ephemeral. The existence of positronium was definitely, though rather indirectly, confirmed in the experiments of Martin Deutsch in 1951.

By analogy with antielectrons (*i.e.*, positrons) it was wondered whether antiprotons exist as well. Such particles, which have the same mass as the proton but a charge of opposite sign, and which can be regarded as holes in a continuum of positive charge, were first detected in 1955 by Owen Chamberlain, Emilio Segrè, Clyde E. Wiegand and Thomas Ypsilantis (*see* ANTIMATTER).

VII. QUANTUM ELECTRODYNAMICS

So far the impression has been given that the relativistic fine structure of hydrogen agreed with the Dirac theory within the limits of accuracy of the measurements. Beginning in 1934, however, there was some indication that the separation between the two peaks of the H α doublet in hydrogen was smaller than predicted by theory. (Each peak of the doublet results from a number of unresolved components, and rather careful analysis is necessary to evaluate properly their combined effect.) Whether there was a real discrepancy was for a number of years a matter of controversy, but painstaking spectroscopic measurements by L. Giulotto and others in 1947-48 made it clear that the discrepancy was real.

At about the same time it occurred to a number of theoretical physicists that an explanation of the discrepancy was that there are corrections because of the interaction of the electron with the electromagnetic field, which is represented in quantum mechanics by a series of quantized oscillators. This is a tricky subject, for the energy associated with this interaction turns out to be infinite, a difficulty which had been appreciated since 1930 and which is known as the divergence in the self-energy of the electron. Nevertheless, by a proper system of bookkeeping, not without elements of arbitrariness and inconsistency, it is possible to compute the differences in the electrodynamic corrections for the various states of the hydrogen atom, and these turn out to be finite. The differential effects agree well with experiment, and so, despite its bothersome divergences, there is more physical reality in the quantum-mechanical formalism of the electromagnetic field than was realized before 1947.

Most of the experimental verification of the quantum electrodynamic theory is concerned with the fine structure of the levels in hydrogen for which the principal quantum number has the value 2. Without the electrodynamic corrections, there are two such levels, given by (24), with $n = 2$ and $k = 1$; or $n = 2$ and $k = 2$. In the uncorrected theory the level $n = 2, k = 1$ actually consists of two coincident states, called $2^2S_{\frac{1}{2}}$, $2^2P_{\frac{1}{2}}$ in the terminology of the spectroscopists; while $n = 2, k = 2$ is designated as $2^2P_{\frac{3}{2}}$. (The subscript gives the value of J , and the letters S, P mean that the so-called azimuthal quantum number has respectively the values 0, 1.) The electrodynamic corrections prove to be practically the same for the two P levels but differ for the S state. As a result the two coinciding levels $2^2S_{\frac{1}{2}}$, $2^2P_{\frac{1}{2}}$ are split apart, and $2^2S_{\frac{1}{2}}$ is displaced toward $2^2P_{\frac{1}{2}}$, a phenomenon known as the Lamb shift. This decomposition is too small to resolve by conventional optical experiments, but makes the apparent doublet width separating the $J = \frac{3}{2}$ state from the $J = \frac{1}{2}$ state smaller than the difference calculated from (24) with the choices $k = 1$ or $k = 2$. The discrepancy with the best optical measurements is thus explained.

Much more quantitative—in fact, spectacular—tests of the electrodynamic corrections have been made, however, with the microwave and molecular beam techniques, which make possible the direct observation of the small energy differences represented by the transitions $2^2S_{\frac{1}{2}} - 2^2P_{\frac{1}{2}}$ and $2^2S_{\frac{1}{2}} - 2^2P_{\frac{3}{2}}$. With ordinary optical measurements, where the wavelength is of the order

0.0001 rather than 10 cm., these intervals can be observed only as small fine structures or modulations in the Balmer series. The microwave measurements require intricate and difficult detection techniques, which Willis E. Lamb, Jr., and Robert C. Retherford successfully devised and instrumented in 1950.

The Lamb shift for hydrogen, $2^2S_{1/2} - 2^2P_{1/2}$, calculated from the electrodynamic corrections is $0.035292 \text{ cm.}^{-1}$ (1057.99 mc.), while in the 1960s the most recent experimental value of Lamb *et al.* was 0.035285. For deuterium (heavy hydrogen) the corresponding figures are 0.035333 and 0.035326. The large number of significant figures for such small energy differences reveals graphically the high precision of microwave and molecular beam spectroscopy. It is a particular triumph both of theory and experiment that there is such good accord (both $0.000041 \text{ cm.}^{-1}$) between the calculated and observed difference in the shift for hydrogen (H^1) and deuterium (H^2), obviously a delicate, high-order correction.

In 1947 Julian Schwinger showed that the electrodynamic corrections make the magnetic moment of the electron somewhat greater than the conventional expression $eh/4\pi mc$. The most accurate theoretical value, inclusive of second order electrodynamic corrections, computed by Charles M. Sommerfield, introduces an extra factor, 1.001159615. Recent electron-beam experiments by D. T. Wilkinson and H. R. Crane give 1.00159622. The difference between the two values is less than either the experimental error or the uncertainty arising from neglect of still higher-order terms in the theory. Earlier molecular beam measurements by Polykarp Kusch and collaborators yielded 1.001146 ± 0.000012 . The work of Lamb and Kusch in confirming quantum electrodynamics won them joint award of the Nobel Prize for Physics in 1955.

A field theory analogous with that of quantum electrodynamics is used to describe the properties of mesons, transient particles of intermediate mass used in the mechanics of the interior of the nucleus. (See also NUCLEAR MOMENTS.)

VIII. WHAT QUANTUM MECHANICS HAS ACCOMPLISHED

By way of summary, it is perhaps well to list some of the outstanding contributions which quantum mechanics has made to the understanding of atomic physics.

1. The old Bohr theory owes its success to quantum mechanics. The great triumph of the original Bohr version of quantum theory was its ability to explain the spectral frequencies of hydrogenic atoms; e.g., hydrogen and ionized helium. This is done equally well by wave mechanics—in fact, better in some respects.

2. Quantum mechanics has provided a procedure for calculating the intensities rather than merely the frequencies of spectral lines.

3. Qualitative explanation of the spectra of nonhydrogenic atoms is now possible. The reason that quantitative precision is usually not possible is simply that when there is more than one electron the wave equation becomes too complicated mathematically to solve exactly. In the particular case of the neutral helium atom, which involves a three-body problem, it is possible to calculate the energy levels very accurately after considerable labour. The computed energy of the ground state of the neutral helium atom agrees with the observed energy to within 1 part in 10,000. This atom, on the other hand, was a stumbling block of the old Bohr theory.

4. Electron spin has played an important part in understanding of the phenomena of magnetism.

5. A quantum theory of the chemical bond has been formulated. Although chemical processes are so complicated that one cannot hope to calculate accurately from theory the heats of the reactions, still quantum mechanics does enable one to understand the salient features—how valence rules hold as they do, how there are saturated bonds, and so on. The Pauli exclusion principle is the key to the interpretation. The spin quantum number of an atom is intimately connected with its valence. Atoms with spins other than zero can be regarded as having unsaturated valences. The bonding is not due to any large magnetic coupling between the spins, and usually arises from the so-called exchange energy, which is electrostatic in character but which is correlated with

spin alignment because of the constraints imposed by the Pauli exclusion principle. As a rule, the exchange energy is favourable to bonding when the spins are antiparallel. Besides codifying valence numbers, quantum mechanics has furnished a qualitative understanding of the directional valence characteristic of stereochemistry. It has also introduced the concept of resonance energy in chemical bonds. Previously the molecule was thought of as having a fixed structure, but quantum mechanics shows that it can coexist in several states at once, and a lower energy is often obtained if a molecule resonates among a variety of configurations.

6. A quantum theory of the solid state has been formulated. Thanks to quantum mechanics, it can be explained in a general way how atoms are held together in solid bodies. Various properties of solids, such as compressibility, thermal and electrical conductivity, specific heat, etc., also can be explained. Because solids involve more complicated aggregates of atoms than do individual molecules, the difficulties in the way of a strictly rigorous numerical computation are even greater than for the calculation of chemical binding. Nevertheless, semiquantitative as well as qualitative predictions are sometimes possible.

7. Quantum mechanics provides the basis for the interpretation of ionization potentials, capture phenomena and especially questions connected with the scattering of electrons or other particles (e.g., neutrons, protons) when they come near atoms or molecules.

8. Numerous phenomena associated with the interaction of radiation with matter were first adequately explained by quantum mechanics. Examples are the Compton effect or the photoelectric effect, and various questions connected with absorption and emission. By means of the so-called Kramers formula, a far more profound and realistic description of dispersion is provided than in classical theory.

9. Quantum mechanics provides an explanation of the existence of the positron and antiproton.

10. A quantum electrodynamics, describing many phenomena associated with radiation and with the coupling of electrons, has been formulated.

11. Finally, the philosophical implications of quantum mechanics must not be forgotten. The Heisenberg uncertainty principle, which shows that there is a limit to the precision with which nature can be observed, is particularly important in this respect.

QUANTZ, JOHANN JOACHIM (1697–1773), German composer who is remembered chiefly as a virtuoso and theorist of the flute, was born at Oberscheden, near Göttingen, on Jan. 30, 1697. As a child he showed musical talent and was taken by his uncle to Merseburg, where he studied several instruments. After the completion of his apprenticeship he obtained posts at Radeberg and later at Dresden, where he studied Vivaldi's violin concertos. In 1717 he took lessons in counterpoint from J. D. Zelenka in Vienna and in 1718 was appointed oboist in the court chapel of the king of Poland. He then took up the practice of the flute, on which instrument he was to become famous. During the years 1723–27 he traveled widely throughout Europe before returning to Dresden. In 1728 he became flute instructor to the crown

prince of Prussia (later Frederick the Great) and when the latter succeeded to the throne in 1741 he persuaded Quantz to settle in Berlin. He remained in Berlin as chamber musician and court composer until his death at Potsdam on July 12, 1773.

Quantz composed about 300 concertos for Frederick the Great, very few of which were ever printed. His important book on flute playing, *Versuch einer Anweisung die Flöte traversiere zu spielen*, published in Berlin in 1752, was reprinted many times. He also wrote an autobiography. Some of his sonatas and concertos were published in the 20th century, and a facsimile of the 3rd German edition of the *Versuch* was published in 1953.

See A. Quantz, J. J. Quantz: *Leben und Werke* (1877); A. Yorke-Long, *Music at Court* (1954). (Cs. Ch.)

QUARANTINE AND ISOLATION. Quarantine is the complete or partial limitation of the freedom of movement of well persons or animals that have been exposed to a communicable disease; its purpose is to prevent further transmission of the disease. Segregation of a sick person or carrier is also commonly called quarantine but is more properly designated isolation.

Venice in 1374 imposed what was probably the first quarantine by banning travelers suspected of having been infected with bubonic plague. In 1377 the Adriatic port of Ragusa (modern Dubrovnik, Yugos.) required all travelers from plague districts to remain for a month at one of two designated points before entering the city. The first quarantine station was erected in 1383 in Marseilles, where all travelers from infected ships were detained for 40 days. It is from this 40-day period of detention that the term quarantine is derived (It. *quaranta*, "forty").

The purpose of isolation is to prevent transmission of the infectious agent from the infected person or animal to a susceptible person by placing the person or animal under such conditions that the possibilities of transmission are minimized. Strict isolation of the patient for the period of communicability (which is determined by experience) is necessary in diseases such as smallpox. In other diseases, such as malaria, the patient need only be protected by screens from the mosquito vector. In still other diseases isolation is not utilized nowadays, either because the method of transmission is not fully understood or because it has been discovered that isolation of the few frank cases of the disease does not prevent further transmission from much larger numbers of mild, unrecognized cases. Modified isolation may be carried on voluntarily by a person's remaining at home when he has a mild infectious disease such as a cold.

While isolation to be effective must be imposed until the end of the period of communicability, the exposed person or animal, called a contact, must not be permitted to expose healthy susceptible persons during the incubation period of the disease. The incubation periods of different diseases or of different cases of the same disease vary in length; but for purposes of quarantine the periods are considered to be the longest usual intervals between first exposure and development of the first signs of infection. Quarantine is often modified so that those contacts who are presumed to be immune because of their ages or histories may be permitted to go about their usual business. Quarantine also is being superseded to some extent by surveillance, the practice of close supervision of contacts so that they may be isolated at the first signs of illness without restricting their freedom prior to that.

Ships usually are no longer quarantined in the earlier manner; the word of the ship's physician is accepted that there are no cases of communicable disease on board. Rapid travel by air, however, has necessitated the institution of new types of quarantine. For example, travelers from an area in which yellow fever is prevalent may be required to remain in quarantine until the end of the incubation period; otherwise they may become sources of infection to the people in the country of their destination.

Quarantine and isolation may be voluntary or official; the latter is enforceable by the government. Official quarantine or isolation is not invoked so often as in the past because in some diseases there are so many unrecognized or missed cases that the identity of the majority of cases and contacts is unknown. When quar-

antine is employed, it usually is enforced to a greater degree against the more susceptible groups in the population or against those who may be dangerous to public health if they become infected; e.g., schoolteachers or food handlers. More efficient methods of controlling communicable disease, such as vaccination (when available) or control of vehicles or vectors of disease, have to a great extent replaced isolation and quarantine.

See American Public Health Association, *Control of Communicable Diseases in Man*, 9th ed. (1960). (H. J. Sv.)

QUARITCH, BERNARD (1819–1899), English bookseller, who in his time developed the largest antiquarian book trade in the world, was born in Worbs, Germany, on April 23, 1819. His whole life was devoted to books. He was a bookseller's assistant, first in Germany, then, from 1842, under H. G. Bohn in London. He set up his own business in 1847 and about 1858 began to deal in rare books including incunabula, Shakespeareana, Bibles, natural history, and travels. Once he had established himself Quaritch left no important book-sale in the world unattended. He had no interests outside books, and there his interest was concentratedly and ruthlessly technical: he cared nothing for content. Quaritch's catalogues were of great bibliographical interest; the first important one, issued in 1873, was the *Bibliotheca Xylographica, Typographica et Palaeographica*, a remarkable collection of early printed books from many countries. He died in London on Dec. 17, 1899. (M. Kl.)

QUARLES, FRANCIS (1592–1644), English religious poet remembered for his *Emblemes and Hieroglyphikes*, the most notable emblem book in English. Born at Romford, Essex, he was baptized on May 8, 1592. He was educated "at schoole in the Countrey," at Cambridge, taking his degree from Christ's College in 1609, and at Lincoln's Inn, London. In 1618 he married Ursula Woodgate, and made his home in London. He had private means, and was happiest living in scholarly seclusion. He began his literary career with a series of lugubrious biblical paraphrases, the first, *A Feast for Wormes*, appearing in 1620. These were collected as *Divine Poems* (1630), his most substantial volume. About 1626 Quarles went to Ireland, where he became secretary to Archbishop Ussher. There he completed his first secular work, *Argalus and Parthenia* (1629), a heroic romance based on a story from Sir Philip Sidney's *Arcadia*. By 1633 he had settled in Essex.

With *Emblemes* (1635) Quarles produced a new type of emblem book. Most of the 79 plates for it, and some of his ideas, were borrowed (though he was a devoted member of the Church of England) from two Jesuit manuals. But his characteristic use of conventional material and the merit of his verse gave the emblem book its initial claim to serious consideration as literature. *Emblemes* was so successful that Quarles produced another emblem book, *Hieroglyphikes of the Life of Man* (1638). Printed together in 1639, *Emblemes* and *Hieroglyphikes* became the most popular book of verse of the 17th century.

The last years of Quarles's life were overshadowed by poverty. Probably for this reason he obtained the post of chronologer to London in 1640, and virtually abandoned poetry to employ his pen more lucratively. His first prose work, *Enchiridion* (1640), became the most popular book of aphorisms of its time.

Civil war found Quarles unhappily conscious of conflicting loyalties, yet a staunch Royalist. He is said to have suffered for his allegiance and for writing *The Loyall Convert* (1644), a pamphlet defending the king's position. Quarles died on Sept. 8, 1644. His wife, with 9 of 18 children who had been born to them, was left in want.

QUARRYING, the art of obtaining stone from the earth's crust. Rocks that are quarried for commercial use fall into three great groups: igneous, sedimentary and metamorphic. Granite is the most important of the igneous type. The sedimentary rocks, of which limestones, sandstones and shales are the most important,

BY COURTESY OF BUREAU OF MINES, U.S. DEPARTMENT OF THE INTERIOR
WIRE SAWS OPERATING IN A GRANITE QUARRY IN MASSACHUSETTS

are sometimes termed stratified because they have been deposited in successive layers. The third group, metamorphic, contains rocks of both igneous and sedimentary origin that have been changed by tremendous mountain-building forces.

There are two main products of the quarrying industries—dimension stone and crushed and broken stone. The term dimension stone is applied to blocks or slabs of natural stone that are cut to definite shapes and sizes. Crushed and broken stone includes irregular fragments produced by passing the stone through crushers or by grinding the rock to a fine powder.

Dimension Stone.—Although rock deposits are abundant, only in certain places have they the necessary qualities that make them suitable for use as dimension stone. Generally the rock must be uniform in grain size and coloration, and must have attractive colours. Most rock deposits are intersected by natural partings called joints. If the joints are closely spaced the rock is valueless. The most favourable deposits are those in which the joints are vertical, in two more or less parallel systems at right angles to each other and spaced four or more feet apart.

When a rock deposit is located the first step is to clear the surface of soil, gravel or other debris—a process known as stripping.

After the surface of the rock has been cleared, the next step is to separate masses of rock from the parent ledge. It is important in quarrying dimension stone to avoid the use of powerful explosives that would shatter the rock and destroy its usefulness. Blocks must be removed with care to preserve their strength and weather resistance. The first operation is to make a cut or channel which will separate a block from the solid bed. For the softer

rocks such as limestones and sandstones, the channeling machine generally is used. This has a cutting tool consisting of several chisel-edged steel bars clamped together. As the power-driven machine travels back and forth on a track, it cuts a channel 2 to 2½ in. wide and several feet deep.

In the harder rocks such as granites, channeling machines cannot be used. One method of making primary cuts in granite, and sometimes in marble and slate, is to drill a row of closely spaced holes to a depth of eight or ten feet, and to cut the webs or cores between them with a flat broaching tool, thus making a continuous channel. Another method is to use a wire saw. This consists of a three-strand or single-strand wire rope about $\frac{3}{8}$ in. in diameter which runs as a belt, and cuts by abrasion when fed with sand or other hard grains in water.

When the primary cuts have been made, if floor seams are absent, the mass of rock must be separated at the quarry floor. Horizontal holes may be drilled beneath the blocks, and the blocks then can be broken loose by driving wedges in the holes. The masses of rock thus set free may be very large. In limestone they may be 80 or 100 ft. long, 8 or 10 ft. high and 4 ft. wide. These large blocks are subdivided into smaller sizes generally by the plug-and-feather method. The blocks are marked out to desired sizes with square and straightedge. A man with a compressed-air hammer drill then sinks a row of shallow holes along the chalk line. Separation is made by wedging. The so-called feathers are tapered lengths of iron curved on one side to fit the wall of the drill hole and used in pairs, one down each side of a drill hole. The plug is a steel wedge which is driven between each pair of feathers. When the plugs are sledged lightly in succession, the force generated is so great that the rock breaks. The separated blocks are conveyed to mills where they are sawed into slabs, shaped to desired dimensions or turned on lathes into columns. They are then rubbed or polished to give the desired surface finish. Jet-piercing, or channeling, techniques, called "burning," also are used for drilling, cutting, shaping, and finishing (see **BLASTING Drilling**).

The principal uses of dimension stone are for both exterior and interior building construction. Granites and marbles are also used extensively for memorials ranging from simple markers and headstones to elaborate mausoleums. Slate is used for roofing, stair treads, blackboards and many other applications. Sandstones are used as building stone and for abrasive wheels such as grindstones. Quartzites are used chiefly for flagging.

Crushed Stone.—Although the use of stone in fragmentary form is a comparatively recent development, the crushed stone industry has far outstripped the dimension stone industry in tonnage. The chief varieties of rock used are limestone, sandstone, granite and basalt (traprock). As the purpose is to obtain small fragments, explosives are used for shattering.

The first operation is to drill deep holes in rows. The churn drill or well drill is widely used to sink holes 6 in. or more in diameter and 50 or more feet deep. The distance of the row of holes from the quarry face is known as the burden; it is commonly 20 to 30 ft. The distance from one hole to another in the row is known as the spacing and is usually less than the burden. In large quarries a row of 15, 20 or more holes, and two or more rows may be drilled for a single blast. The size of the charge in each hole is calculated according to the toughness of the rock. When the explosive charge is in place the upper part of the hole is tamped with sand or rock dust. The charges are fired simultaneously and a single blast may throw down 20,000 or more tons of broken stone, which is then conveyed to the crushers where it is reduced to a maximum size of about six inches. The fines are separated by screening, and the larger sizes are reduced in smaller secondary crushers (see **CRUSHING AND GRINDING MACHINES**). Crushed stone is used chiefly for road building, concrete aggregate and railroad track ballast. Limestone has special uses such as fluxing stone in blast furnaces and for many chemical applications. See also **MARBLE**; **SLATE**; etc.

QUARTER DAYS, the days that begin each quarter of the year; in England, March 25 (Lady Day), June 24 (Midsummer Day), Sept. 29 (Michaelmas Day), and Dec. 25 (Christmas Day). Some local variations of these dates are found. They are the days on which it is usually contracted that rents should be paid and houses or lands entered upon or quitted. In Scotland there are two legal terms, May 15 (Whitsunday) and Nov. 11 (Martinmas); these, with the two conventional terms, Feb. 2 (Candlemas) and Aug. 1 (Lammas), make up the Scottish quarter days. In the Scottish burghs, however, the removal terms are May 28 and Nov. 28. In the United States the quarter days are, in law, the 1st of January, April, July, and October.

QUARTERMASTER. In the U.S. army before 1962 this term denoted a member, usually a commissioned officer, of the quartermaster corps, which was responsible for the procurement and supply of food, clothing, fuel, and individual and housekeeping types of equipment (but not weapons), the collection and interment of war dead, and the maintenance of national cemeteries. A sweeping reorganization of the army's headquarters and field establishment in 1962 eliminated most of the technical services, including the quartermaster corps. Most of the corps' supply functions were absorbed by a new army materiel command, while its procurement functions fell largely to an interservice organization, the defense supply agency. The army continued, however, to commission quartermaster branch officers and to employ quartermaster troop units and quartermaster staff officers in the field.

The term quartermaster has a long history in European warfare, dating back at least to the 15th century. In general, quartermasters superintended arrangements for the quartering, and sometimes the subsistence and movement, of troops. In Europe, quartermaster officials on the staffs of higher commanders had evolved by the 18th century into something like the modern chief of staff, or chief of the general staff. In Great Britain and the United States, by contrast, the quartermaster remained a specialized administrative and logistical functionary. (See *LOGISTICS*.)

The U.S. army's quartermaster corps traces its beginnings to June 1775, when the army itself was first established. From the beginning, the basic function of the quartermaster organization was to help plan marches, lay out camps and provide the army's transportation. In 1812 the quartermaster department (as it was then called) acquired broad though ill-defined purchasing responsibilities that conflicted with those assigned to the commissary general of purchases.

By 1842, however, the quartermaster's department was procuring and distributing to the army all its noncombat supplies and equipment except food, which was the responsibility of the subsistence department. During the Civil War the quartermaster general was responsible for all the army's transportation, on water as well as land, and including all its animals with their forage and equipage. He was also responsible for providing clothing; for the operation of utilities at military camps; for military real estate and construction, except fortifications and railway bridges; for operation of military telegraphs; and for interment of war dead. His control of military railroads and military telegraphs was purely nominal, however, as both these services were operated as virtually independent agencies directly under the secretary of war.

On the eve of World War I the quartermaster corps (now so designated) absorbed the functions of the subsistence and pay departments. During the war, all supply and transportation functions were temporarily concentrated in the general staff, but under the National Defense act of 1920 the corps was re-established with most of its old responsibilities (except the pay function). World War II brought a significant reduction in the scope of these responsibilities through creation of a separate transportation corps and assignment of most types of military construction to the corps of engineers. By 1950 the quartermaster corps had thus become essentially a supply service, feeding, clothing and fueling the army and providing much of its noncombat equipment. Under a broadening system of interservice pooling of logistical responsibilities, some of these functions were also performed for the navy and the air force.

The U.S. quartermaster corps has no exact counterpart in the British service. The royal army service corps (R.A.S.C.) stores and issues expendable noncombat supplies such as food, forage and fuel. The R.A.S.C. is also responsible for most transportation except that organic to units. The royal army ordnance corps stores and issues equipment, clothing, ammunition and explosives and certain motor vehicles. The civilian ministry of supply, rather than the military services, handles procurement of supplies. In British army staff organization, the quartermaster general's branch, or "Q" staff, has co-ordinating responsibility for supplying the material needs of troops and for all military movement (except operational, which is controlled by the "G" or general staff branch). Personnel administration is the responsibility of the adjutant general's branch, or "A" staff.

In the naval service, both American and British, quartermasters are petty officers or selected seamen who perform certain navigational and administrative duties under supervision of the captain, navigating officer or officer of the deck, including manning the wheel while at sea.

QUARTER SESSIONS, COURT OF, in English law, the name of the court held in general or quarterly sessions by the justices of the peace for a county (or riding, parts, liberty, or other division of a county); or of the court held, before a recorder, in a borough having a separate court of quarter sessions (*i.e.*, separate from that of the county in which the borough is geographically situated). The borough may be a county borough, a so-called county of a city or county of a town, or simply a municipal borough. The term "general" applied to sessions contrasts historically with "special" or "petty"; the latter is now reserved for sittings of magistrates in courts of summary jurisdiction and the former is virtually obsolete.

The name quarter sessions is derived from a statute of 1388, which required "the justices to keep their sessions in every quarter at the least." By the Criminal Justice Administration Act, 1962 (section 4 [1]), courts of quarter sessions shall be held at such times as directed by the county justices, the recorder or the lord chancellor; but at least four times a year. The intention, in accordance with the Streatfield Report (Report of the Interdepartmental Committee on the Business of the Criminal Courts, Cmnd. 1289, 1961), is to arrange all the sittings of the various courts of quarter sessions in a given county so that there is at least one court sitting every four or six weeks and a speedy trial can be provided for all prisoners. To ensure this the county and borough sessions dovetail their sittings, and the committing justices (by sections 14 and 15 of the above act) have power to commit to any "convenient" court; *i.e.*, a court that will be sitting earlier than the one to which they normally commit.

Every portion of England and Wales is within the jurisdiction of some court of quarter sessions, and justices and recorders may hold additional sessions by adjourning from time to time. If there is no business to transact within five days of the day appointed for holding the sessions (which is not believed to have happened for many years), the court is not held, and jurymen who have been summoned are excused from attendance (Assizes and Quarter Sessions Act, 1908, s. 1 and 2).

A borough recorder is appointed by the crown on the advice of the lord chancellor and must be a barrister of at least five years' standing. Deputy recorders may be appointed if the recorder is unable to attend; and assistant recorders may be appointed in towns of such a size that the business regularly requires two courts. In county sessions the justices may now elect a chairman and as many deputy chairmen as are necessary. Originally the chairman or deputies were elected by the justices from among their own number and did not have to be legally qualified. But it was felt that laymen, however experienced, ought not to preside at trials where difficult issues might have to be explained to a jury or long sentences might have to be passed. By the Administration of Justice (Miscellaneous Provisions) Act, 1938 (s. 1, 2, 4), the

county justices were authorized to request the crown to appoint legally qualified chairmen and deputy chairmen, and to pay them out of county funds, sessions held under such chairmen having increased jurisdiction. By the Criminal Justice Administration Act, 1962 (s. 5), all chairmen and deputy chairmen must be legally qualified, and the jurisdiction of county sessions was further enlarged (s. 12). All recorders, their deputies, and assistants are legally qualified, and their courts have the same jurisdiction as county sessions. A recorder sits alone. Normally county justices must form a quorum (at least two and not more than nine); but if other justices cannot attend, the chairman or his deputy may sit alone.

In Greater London and in Lancashire pressure of work led to the appointment from the bar of whole-time, paid, professional judges; other legally qualified chairmen of county sessions retain their practices. Pressure of work also led to changes in Manchester and Liverpool; in those cities the Criminal Justice Administration Act, 1956, created special criminal courts, known as crown courts, the jurisdiction of the courts of quarter sessions being transferred to the new courts, both of which have full-time judges. Quarter sessions for the City of London are nominally held before the lord mayor and aldermen sitting with the recorder of London, but criminal cases are sent to the central criminal court.

Every court of quarter sessions is a court of record and can punish summarily contempts of itself. It is, however, subject to the supervisory jurisdiction of the Queen's Bench Division of the High Court by means of the prerogative orders. Appeal lies to the Court of Criminal Appeal in respect of all decisions in criminal matters and in other matters by way of case stated to the divisional court.

Criminal Jurisdiction.—An order in council dated Feb. 22, 1878, authorized justices to inquire "of all and all manner of crimes, trespasses and all and singular other offences that the justices of our peace may or ought lawfully to inquire . . ." In fact the jurisdiction is largely statutory. The Quarter Sessions Act, 1842, was the first attempt systematically to regulate (s. 1) the powers of quarter sessions, and it took away their power to try crimes involving a death sentence, long terms of imprisonment, or difficult legal issues. Thereafter a series of statutes alternately added to and reduced the list of crimes triable in sessions. The Criminal Justice Act, 1925, made a valiant effort to rationalize the position, but the acts of 1938 and 1962 (see above) both further enlarged the jurisdiction of sessions. Differences in jurisdiction between various borough quarter sessions were eliminated by legislation in 1956. By the mid-1960s all sessions could try all indictable crimes save treason and kindred offenses; murder; manslaughter; the graver offenses against the person and property and those involving difficult points of law. The list is somewhat piecemeal, arbitrary, and highly technical. Where there is a plea of not guilty the trial is conducted with a jury.

Appellate Jurisdiction.—A recorder can hear appeals from decisions of the borough justices, and county sessions hear appeals from all the petty sessional divisions of the county. Appeals committees, originally created to relieve pressure of work on county sessions, have been abolished, as it was hoped that the more frequent sittings of all sessions would reduce the pressure of work. Such appeals include civil and criminal causes.

Civil Jurisdiction.—Until 1888 the justices in general sessions had wide powers to "conduct the county business," but since then most of their administrative work has been transferred to county councils or other local government bodies, and their civil business now consists of a number of miscellaneous duties that have survived for historical reasons; e.g., the giving of orders relating to the diversion of highways, the appointment of prison visitors, and the hearing of appeals from local justices in civil matters (such as the refusal of a licence for a camping site). As regards the sale of alcoholic liquors, the justices' chief task is to hear appeals from local licensing justices. Their rating functions have been transferred to special tribunals.

United States.—Pennsylvania has courts of quarter session, oyer and terminer, on a county basis; Kentucky has quarterly courts, sharing with city, justice, and police courts jurisdiction

over certain classes of cases. Otherwise, courts of other names, differing in the various jurisdictions, perform the functions of the English courts of quarter sessions. See also COURT.

(G. A. F.)

QUARTER SQUARES. The product of two numbers is equal to the difference of one fourth the squares of their sum and their difference: $ab = \frac{1}{4}(a+b)^2 - \frac{1}{4}(a-b)^2$. This fact has been used to reduce multiplication to addition with the aid of tables of quarter squares, or using other methods of generating quarter squares. The quarter square of an odd number always has a fractional part $\frac{1}{4}$, which can be ignored in applying the formula. The method is very old and many tables of quarter squares have been prepared, but few are easily available. The most extensive table lists quarter squares of integers not exceeding 200,000. Various mechanical and electrical applications have been suggested. The method is still frequently useful and economical.

See J. Blater, *Tafel der Viertel-Quadrate aller ganzen Zahlen von 1 bis 200,000* (1887). For reference to other tables see A. Fletcher, J. C. P. Miller, L. Rosenhead, *An Index of Mathematical Tables* (1946 and later) and mathematical review journals. (C. B. To.)

QUARTON (CHARONTON, CHARRETTON), **ENGUER-RAND**, French religious painter, famous for his "Coronation of the Virgin," was born in the diocese of Laon, and was active in Provence (1444-66). His real name was transformed in the south into Charonton or Charretier and in modern times, with no reason, into Charonton or Charenton. He is one of the best-documented French medieval artists and details exist of six commissions for important paintings, two of which have survived: the "Virgin of Mercy" (1452, Chantilly), an altarpiece, the predella of which, painted in collaboration with Pierre Villate, is missing; and the "Coronation of the Virgin" (1453-54, Hospice de Villeneuve-les-Avignons), the contract for which is one of the most complete and interesting documents on medieval art, showing that the composition was minutely prescribed. Both paintings reveal a very original style, partly northern (showing affinities with the tapestries of Arras and sculptures from Picardy) and partly southern (a sort of "Cubist," sharp, sculptural stylization of figures, folds and rocks). Exactly the same style is to be found in the famous "Avignon Pietà" (shortly before 1457? now in the Louvre), which is most probably the work of Quarton.

Quarton is in the first rank of French painters. He is full of imagination, creating very original types of Virgin and saints; his drawing is precise and graceful, his composition majestic and rich. Like Jean Fouquet, Quarton combines the grandeur of monumental decoration with the subtlety of book illumination.

QUARTZ, a widely distributed mineral species, consisting of silicon dioxide, or silica (SiO_2). It is one of the commonest minerals and is found in many varieties and with very diverse modes of occurrence. The various forms of quartz have attracted attention from the earliest times, and the water-clear crystals were known to the Greeks as *crystallos*, "clear ice," being supposed by them to have been formed from water by the intense cold of the Alps; hence the name crystal, or more commonly rock crystal, applied to this variety. The name quartz is an old German word of uncertain origin, first used by Georg Agricola in 1530.

Following a description of the uses, occurrence and general properties of quartz this article deals with its crystallography, the varieties of quartz, electrical properties and optical properties and discusses the changes, known as inversions, quartz undergoes when heated.

Uses.—Quartz is a mineral of great economic importance. Many varieties are in popular use as gem stones, such as agate, amethyst, aventurine, bloodstone, cairngorm or smoky quartz, carnelian, chrysoprase, citrine, onyx (for cameos), rock crystal, rose quartz and tigereye (see also GEM). In localities where satisfactory material is available, sandstone, composed mainly of quartz, is an important building stone. Large amounts of sand are used in the manufacture of glass and porcelain. Sand is widely

used for foundry molds for casting metals. Quartz is an abrasive, as in sandpaper, sandblasting, millstones and grindstones. Quartz brick is a high-grade refractory (see *Inversion*, below) and is used as a flux in smelting calcareous ores. Both quartz and silica glass transmit ultraviolet light and are used optically for this purpose. Because of the low coefficient of expansion and the refractory nature, tubing and various vessels of fused quartz have important laboratory applications; fibres are used in extremely sensitive weighing devices (see *BALANCE: Ultramicrobalance*). Thin plates cut from quartz crystals are used for frequency control in electronic communications equipment (see *Electrical Properties*, below).

Occurrence.—Quartz occurs as a primary and essential constituent of igneous rocks of acidic composition, such as granite, quartz porphyry and rhyolite. It is an abundant mineral in pegmatites, sometimes making up the major part, and often being intergrown with feldspar (graphic granite). It is a common constituent in many gneisses and crystalline schists. By the weathering of silicates, silica passes into solution and is redeposited as quartz in cavities, crevices and along joints of rocks of all types. Extensive veins of quartz are frequent in schistose rocks.

Quartz veins, of economic importance as a matrix of gold, are probably related to igneous action. In mineral veins and lodes, quartz is often the most abundant gangue mineral. Quartz, being a mineral very resistant to weathering, forms the bulk of sands and sandstones, the latter being sand cemented with calcite, gypsum or hematite. A siliceous cement gives an orthoquartzite, while such a rock after being metamorphosed and recrystallized is called metaquartzite. Quartz occurs as pseudomorphs, replacing other minerals, and frequently is the petrifying material in petrified wood.

For ordinary uses, quartz is abundant and cheap. However, lack of adequate supplies of suitable crystals for electrical use has led to many attempts to grow synthetic quartz. Successful methods have been found, and good crystals, free from twinning, have been produced.

General Properties.—Quartz is a hardness standard, being 7 on Mohs' scale; it cannot be scratched with a knife. The specific gravity is 2.65. There is no distinct cleavage, but plunging a heated crystal into cold water may develop planes of separation parallel to the rhombohedral and prism faces. A conchoidal fracture is characteristic of most varieties. Coarse-grained varieties have a vitreous to greasy lustre; fine-grained varieties may be waxy or dull. The mineral is a nonconductor of electricity; it is not attacked by acids, except hydrofluoric, and is only slightly dissolved by solutions of caustic alkalis. It is infusible in the ordinary blowpipe flame, but will fuse in the oxyhydrogen flame to a clear colourless glass.

Crystallography.—Quartz crystallizes in the trigonal trapezohedral class of the hexagonal system. The crystals possess no planes or centre of symmetry, but only axes of symmetry. The vertical (*c*) axis is a threefold axis, and the three lateral (*a*) axes are twofold and polar; that is, the opposite ends are not alike. Usually, however, this lower degree of symmetry is not indicated

FIG. 2.—LEFT- AND RIGHT-HANDED QUARTZ CRYSTALS ILLUSTRATING MIRROR IMAGE SYMMETRY

by the face development of the crystals. Many crystals are bounded only by the faces of a hexagonal prism *m* ($10\bar{1}0$) and what appears to be a hexagonal bipyramid (fig. 1A), although sometimes the prism is absent (fig. 1B). Frequently the crystals are distorted (fig. 1C), with similar faces varying in size but still having their proper angular positions. If the distortion is extreme, at first glance the crystals may be difficult to interpret, but they can usually be oriented by aid of the very characteristic horizontal striations on the prism faces. These striations (fig. 1C) are parallel to the edges of intersection between the prism and terminal faces, and are due to the frequent oscillatory combination of these forms. The apparent hexagonal bipyramid is really a combination of two rhombohedrons, one positive, *r* ($10\bar{1}1$), and the other negative, *s* ($01\bar{1}1$). Although many exceptions occur, *s* is usually smaller than *r* (fig. 2A and B) and sometimes completely absent. The six small faces *s* ($11\bar{2}1$), situated on alternate corners, are those of a trigonal bipyramid, while the faces *x* ($51\bar{6}1$) are those of a trigonal trapezohedron. The latter are of comparatively rare occurrence, except on crystals from a few localities. These *x* faces clearly distinguish between the two types of quartz crystals, left-handed (fig. 2A) and right-handed (fig. 2B). Such crystals are said to be enantiomorphous. They are not superposable, but one is the mirror reflection of the other, like the right and left hands. In some cases the *s* faces are striated parallel to their intersection with *r*; this serves to distinguish *r* and *s*, and thus show the right- or left-handed character when the *x* faces are missing. Numerous other faces have been observed on quartz, but they are of rare occurrence. The basal plane, so common on many crystals, is of the greatest rarity on quartz, and when present appears only as a small rough face formed by corrosion of the crystal. Natural etching, or artificial etching by hydrofluoric acid, produces etch figures, which are small pits or depressions of characteristic shape. As would be expected, the etch figures are different on the *r* and *s* faces, and on right-handed crystals the etch figures are reversed in position with respect to left-handed, thus clearly revealing the true symmetry and enantiomorphous character. This feature of the crystals is of course related to the internal grouping of the atoms, which actually consists of a spiral arrangement that may be either right- or left-handed.

Twin crystals of quartz are very common; in fact those without twinning are rare. The twinning may not be obvious unless the *s* or the *x* faces are present. Penetration twins are the commonest, with the prism planes of both individuals coinciding, and may be of two types. Dauphiné or electrical twins consist of two right-handed or two left-handed crystals intergrown so that the *r* faces of one coincide with the *s* faces of the other, which brings the *x* and *s* faces on all six corners, both above and below. The contact between the two portions may be very irregular, or there may be a complicated patchwork of the two orientations. Brazil or optical twins are intimate intergrowths of right- and left-handed quartz, laminae or polygonal inclusions of one being en-

FIG. 1.—QUARTZ CRYSTALS SHOWING RELATIONSHIPS OF FACES AND CHARACTERISTIC STRIATIONS

closed within the other. These twins are readily detected by use of polarized light. Both types of twinning may be present in the same crystal. Dauphiné twinning is revealed by etching with hydrofluoric acid, and sometimes, probably as a result of natural etching, it is possible to trace the twin boundaries between duller z and brighter r areas in the same plane. In a rarer type in which the twin plane is (112), two individuals are united in juxtaposition with their vertical axes nearly at right angles ($84^\circ 33'$). Such twins have been found in Isère, in the former province of Dauphiné, France, and in Japan they are fairly abundant.

Varieties.—Quartz crystals have many interesting variations. They may show a skeletal development, or they may have a helical twist. They may have successive layers of growth. If transparent, the outlines of the inner layers may be faintly visible, giving a "phantom" crystal. In "cap" quartz, the successive layers may be separate. "Sceptre" quartz has a short, thick crystal perched in parallel position on a longer slender crystal. Many crystals have cavities, usually filled with a liquid (water, carbon dioxide or a hydrocarbon) and containing a movable bubble of gas. Among the many varieties of quartz are amethyst, rose, milky and smoky quartz, which have characteristic colorations. In addition to the pink colour, properly cut rose quartz may show a star-shaped figure (asterism). Citrine is a yellow variety. Some types of quartz contain inclusions of other minerals, such as rutiled quartz, which has long needles of rutile. Aventurine contains glistening scales of mica, hematite or chlorite; moss agate has inclusions of manganese oxide or chlorite. Tigereye is a replacement of asbestos, and retains the fibrous structure; hence it has a beautiful chatoyant (cat's-eye) lustre when cut and polished. There are many fine-grained varieties of quartz. Chalcedony has a waxy lustre, and occurs in botryoidal and stalactitic forms. Agate and onyx are banded, being formed by the successive deposition of very thin layers. Many agates used for ornaments have been artificially coloured. Carnelian is red; chrysoprase and plasma are green; bloodstone is green with red spots. Basanite or touchstone is black, and was formerly used for testing precious alloys by means of the colour of the streak they left when rubbed on the stone. Jasper is impure, and coloured red, brown or yellow by iron oxide. Flint and chert are gray and occur as nodules in chalk and limestone. For particulars concerning the appearance, properties, occurrence, etc., of varieties of quartz see AGATE; AVENTURINE; BLOODSTONE (or heliotrope); CARNELIAN; CAT'S-EYE; CHERT AND FLINT; JASPER; MOCHA STONE (or moss agate); ONYX.

Electrical Properties.—Quartz is piezoelectric; that is, a crystal develops positive and negative charges on alternate prism edges when it is subjected to pressure or tension. The charges are proportional to the change in pressure. The pyroelectric effect supposedly observed on quartz is actually attributable to differential expansion during heating, hence is really a piezoelectric effect. This behaviour is related to the low symmetry, especially to the polar character of the lateral axes. Because of the piezoelectric property, a quartz plate can be used as a pressure gauge, as in depth-sounding apparatus. Moreover, if compression and tension produce opposite charges, the converse effect is that alternating opposite charges will cause alternating expansion and contraction. A section cut from a quartz crystal, with definite orientation and dimensions, has a natural frequency of this expansion and contraction (*i.e.*, vibration) which is very high.

Properly cut plates of quartz may have frequencies measured in millions of vibrations per second, and are used for frequency control in radio and other electronic communications equipment and for crystal-controlled clocks. Quartz plates for this purpose must be from portions of a crystal free from twinning (electronic grade); otherwise the vibrations would be in opposition in the two twin areas.

Optical Properties.—In its optical behaviour, quartz is also of interest, since it shows rotary polarization. This phenomenon is related to the enantiomorphous character of quartz. A ray of plane-polarized light traversing a right-handed crystal in the direction of the vertical axis has the plane of polarization rotated to the right, while a left-handed crystal rotates it to the left. A

section one millimetre thick, cut perpendicular to the vertical axis of a quartz crystal, rotates the plane of yellow light (D line) through 22° and of blue light (G line) through 43° . Such a section when examined between crossed nicols with the petrographic microscope shows an interference figure with a coloured centre, there being no black cross inside the innermost ring (this is not shown in very thin sections). Superimposed sections of right- and left-handed quartz, as may be present in twinned crystals, exhibit interference figures with Airy spirals. The indexes of refraction of quartz for yellow light (D) are $n_o = 1.5442$ and $n_e = 1.5533$; the optic sign is therefore positive.

See also LIGHT: *Refraction and Double Refraction; Natural Optical Gyration.*

Inversion.—When heated, quartz undergoes a series of remarkable changes. At ordinary temperatures it exists as α -quartz, but at 573° C. it passes over into β -quartz, with a change from trigonal trapezohedral to hexagonal trapezohedral symmetry and an alteration in other properties. At 867° C. this β -quartz changes to β -tridymite, and again at $1,470^\circ$ C. changes to β -cristobalite. These changes are known as inversions. The inversion from α - to β -quartz is reversible, so that quartz is always the α -form at ordinary temperatures. After β -tridymite or β -cristobalite are formed, they remain as tridymite or cristobalite, but upon cooling they invert to metastable α forms, which may exist for indefinitely long periods. Accordingly, all three α forms are found in nature. The six crystalline modifications have closely related structures, in which each silicon atom is surrounded tetrahedrally by four oxygen atoms. Adjacent tetrahedrons are linked by sharing of oxygen atoms, and the various modifications differ only in the arrangement of these linked tetrahedrons. The change from quartz to tridymite at the inversion temperature is very sluggish. This is of practical importance in the manufacture of silica refractory brick. The original quartz brick must be heated well above the inversion temperature if the inversion is to be completed in a reasonable time. This is necessary before the brick can be used in a furnace lining, since there is about a 15% increase in volume in the inversion from quartz to tridymite. Cristobalite, on the other hand, has nearly the same volume as tridymite, so that it does not matter which is present in the finished brick. For additional information on inversion see SILICA.

For discussion of crystallographic and mineralogical concepts used in this article see also MINERALOGY. See also references under "Quartz" in the Index. (L. J. S.; L. S. R.)

QUARTZITE is a sandstone which has been converted into a solid quartz rock. Unlike sandstones, quartzites are free from pores and have a smooth fracture; if struck with a hammer they break through the sand grains, whereas in sandstones the fracture passes through the cementing material and the rounded surfaces of the grains are exposed, giving the broken surface a rough and granular appearance. Conversion of sandstone to quartzite may be accomplished by precipitation of silica from interstitial waters (hydrous metamorphism) at no great depth and under ordinary pressures. In contrast with these rocks, termed orthoquartzites, those produced by recrystallization under high pressure and elevated temperatures are called metaquartzites.

In microscopic section the clastic structure of some quartzites is well preserved; the rounded sand grains are seen with quartz overgrowths deposited in crystalline continuity so that the optical properties of the grains are similar to those of the material which surrounds them: a line of iron oxides or other impurities may indicate the boundary of the original sand grain. Many quartzites, however, have been crushed and the quartz consists in large part of a mosaic of small crystalline fragments of irregular shape with interlocking margins; these are the "sheared quartzites"; and if they contain white mica in parallel crystalline flakes they become more fissile and pass into quartz schists.

The term quartzite implies not only a high degree of induration or "welding" but also a high content of quartz. Rocks of like induration but containing appreciable quantities of other minerals and rock particles are impure quartzites, more appropriately called graywacke, etc. Most quartzites contain 90% or more of quartz, and in some the quartz content exceeds 99%. These constitute the

largest and purest concentrations of silica in the earth's crust. Quartzites are snowy white, less often pink or gray; they commonly have a fine angular jointing and break up into rubble under the action of frost. They yield a thin and very barren soil, and because they weather slowly tend to project as hills or as mountain masses. Many of the prominent ridges in the Appalachian mountains are the topographic expression of highly resistant tilted beds of Paleozoic quartzite. The Precambrian rocks of the Lake Huron and Lake Superior regions include thick and very pure quartzites. The Baraboo quartzite in Wisconsin is often deep red in colour. In Scotland, the mountains of Schiehallion in Perth and the Paps of Jura form conspicuous conical mountains of quartzite in the Dalradian system of the highlands and Cambrian quartzites cap mountains in western Sutherland. The pure quartzites are a source of silica for metallurgical purposes and for the manufacture of silica brick. Quartzite is also quarried for paving blocks, riprap, road metal (crushed stone), railroad ballast and roofing granules.

(F. J. P.; X.)

QUARTZ PORPHYRY, in petrology, a group of acidic igneous rocks that are porphyritic, that is, composed of larger crystals in a fine-grained groundmass. They contain visible crystals of quartz in a fine-grained matrix which is usually minutely crystalline in structure. In hand specimens the quartz appears as small, rounded, clear, grayish, vitreous blebs, which are crystals (double hexagonal pyramids) with their edges and corners rounded by resorption or corrosion. Under the microscope rounded enclosures of the groundmass or fluid cavities are often seen; these frequently have regular outlines resembling those of perfect quartz crystals and are known as negative crystals. Many of the quartz crystals contain liquid carbonic acid and a bubble of gas which may exhibit vibration under high magnifying powers. In addition to quartz there are usually prominent crystals (phenocrysts) of feldspar, mostly orthoclase, though a varying amount of plagioclase is often present. The feldspars are usually cloudy from the formation of secondary kaolin and muscovite throughout their substance; their crystals are larger than those of quartz and sometimes attain a length of two inches. It is not uncommon for scales of mica to be visible as hexagonal plates. Other porphyritic minerals are few, but hornblende (an amphibole), and augite and bronzite (pyroxenes) are sometimes found; the augite and hornblende are in most cases green, and are frequently decomposed into chlorite, but even then can usually be identified by their shape. A colourless rhombic pyroxene (enstatite or bronzite) occurs in a limited number of the rocks of this group and readily weathers to bastite, a variety of chlorite.

Apatite, magnetite and zircon, all in small but frequently perfect crystals, are almost universal minerals of the quartz porphyries.

Structure.—The groundmass is finely crystalline. To the unaided eye it usually appears dull, resembling common earthenware; it is gray, green, reddish or white. Often it is streaked or banded by fluxion during cooling but as a rule these rocks are not vesicular. Two main types may be recognized by means of the microscope—the felsitic and the microcrystalline. In the former the ingredients are so fine grained that even in the thinnest slices they cannot be identified under the microscope. Some of the rocks show perlitic or spherulitic structure; such were probably originally glassy (obsidians or pitchstones), but by lapse of time have slowly passed into a very finely crystalline state. This change is called devitrification; it is common in glasses, as these are essentially unstable. A large number of the finer quartz porphyries are also in some degree silicified or impregnated by quartz, chalcedony and opal, derived from the silica set free by decomposition (kaolinization) of the original feldspar. This redeposited silica forms veins and patches of indefinite shape or may bodily replace a considerable area of the rock by metasomatic substitution. The opal is amorphous, the chalcedony finely crystalline and often arranged in spherulitic growths which yield an excellent black cross in polarized light.

The microcrystalline groundmasses are those which can be resolved into their component minerals in thin slices by use of the microscope. They prove to consist essentially of quartz and feld-

spars, which are often in grains of quite irregular shape (microgranitic). In other cases these two minerals are in graphic intergrowth, often forming radiate growths of spherulites consisting of fibres of extreme slenderness; this type is known as granophyric. There is another group in which the matrix contains small rounded or shapeless patches of quartz in which many rectangular feldspars are embedded; this structure is called micropoikilitic (from the Greek for variegated or mottled), and though often primary is sometimes developed by secondary changes which involve the deposit of new quartz in the groundmass. As a whole those quartz porphyries which have microcrystalline groundmasses are rocks of intrusive origin.

Older Forms.—Many of the older quartz porphyries which occur in Paleozoic and Precambrian rocks have been affected by earth movements and have experienced crushing and shearing. In this way they become schistose, and from their feldspar minute plates of sericitic white mica are developed, giving the rock in some cases very much of the appearance of mica schists. If there have been no phenocrysts in the original rock, very perfect mica schists may be produced, which can hardly be distinguished from sedimentary schists, though chemically somewhat different on account of the larger amounts of alkalis which igneous rocks contain. When phenocrysts were present they often remain, though rounded and dragged apart while the matrix flows around them. The glassy or felsitic enclosures in the quartz are then very suggestive of an igneous origin for the rock. Such porphyry schists have been called porphyroids or porphyroid schists, and in North America the name aporhyolite has been used for them. They are well known in some parts of the Alps, Westphalia, Charnwood (England) and Pennsylvania. The *hällsfintas* of Sweden are also in part acid igneous rocks with a well-banded schistose or granulitic texture.

The quartz porphyries are distinguished from the rhyolites by being intrusive rocks.

QUASIMODO, SALVATORE (1901–), Italian poet who received the Nobel prize for literature in 1959. He was born at Modica, Sicily, on Aug. 20, 1901, and had a technical education, which may explain the enthusiasm for technological progress of his later poems. After graduating in engineering at the Rome polytechnic, he spent ten years in different parts of Italy in the state engineering service's department of geometrical design, writing poetry in his spare time.

In 1935 he settled in Milan where he was appointed professor of Italian literature at the Conservatoire. Later he became dramatic critic for the Milan *Tempo* and a regular contributor to various reviews.

Quasimodo published his first poems in the *avant-garde* review *Solaria*. In the 1930s he became a leader of the *ermetismo*, a school of poetry which derived from the French Symbolistes an experimental attitude to verse form and the theory that words should be used to convey unconscious associations of feeling and thought by being linked in unexpected arrangements. At first a disciple of G. Ungaretti and E. Montale (*q.v.*), he soon developed a personal style with its own haunting music, introducing into the frigid and calculated skill of his technical innovations a human warmth and a consciousness of the mysterious power of man's ancestral hopes and fears. From *Acque e terre* ("Waters and Land," 1930) to *La terra impareggiabile* ("The Incomparable Earth," 1958) Quasimodo's poetry showed coherent development from a dry, sophisticated perfection of style to understanding of life and a commitment to contemporary struggles, expressed in his statement, "The ultimate conquest of poetry is reality." In his translations, notably *Lirici Greci* (1940), *Il fiore delle Georgiche* (1942) and *La Tempesta* (1952) he combined feeling for the original with modern taste and sensibility.

(F. M.)

QUASI-STELLAR RADIO SOURCES are bizarre astronomical objects which radiate prodigious amounts of radio and optical energy. First detected in 1961, these sources, hereafter called QSS's, represent one of the fundamental astronomical discoveries of the 20th century. They present a combination of characteristics unlike anything previously known in the universe and

may be the first evidence of the existence of a new type of energy source.

The QSS's generate continuous radio power at all the frequencies that can be received on earth. The energy distribution in optical wavelengths shows an abnormal ultraviolet flux compared with other known astronomical bodies. The emission lines in the optical spectra—due to hydrogen, magnesium, and highly ionized neon and oxygen—are all shifted from their laboratory wavelengths toward the red, indicating large velocities of recession, apparently caused by the cosmological expansion of the universe. These red shifts range from $\Delta\lambda/\lambda_0 = 0.158$ for source 3C 273 to $\Delta\lambda/\lambda_0 = 0.545$ for source 3C 147. If cosmological in origin, these red shifts indicate that the QSS's are more than 1,000,000,000 light-years distant from our galactic system. These distances, calculated from the velocity-distance relation, combined with the flux density of radiation measured on earth, show that the power generated by each QSS is about 4×10^{46} ergs per second, which is of the order of 100 times the total power radiated by the largest galaxies known. The diameters of the QSS's are probably less than 150 parsecs, which is exceedingly small for objects producing power at the observed rate. Furthermore, the light of the QSS's varies in intensity by about 40% over periods of about three years. How the most powerful sources of energy known can change their power output by such an enormous factor in such a short time is not understood.

The mechanism of radio generation is believed to be due to the acceleration of ultra-high-speed electrons in a large-scale magnetic field associated with the QSS's. The origin of the electrons themselves is likely to be connected with a gigantic explosion which transferred energy from the explosive mechanism into the elementary particles created by the catastrophe. The debris of the explosion can be seen optically in the thin, luminous jets which are present in QSS 3C 48, 3C 196, 3C 273, and several others. These jets extend outward to distances of about 300,000 light-years from their parent bodies. These distances indicate that the minimum age of the QSS's is 300,000 years, obtained by assuming that the material comprising the jet escaped from the central object at the speed of light at the time of the explosion. But the true lifetime is likely to be considerably longer because the jets must have traveled more slowly than light.

A minimum value for the energy radiated by the high-speed electrons can be calculated to be 4×10^{59} ergs, obtained by multiplying the radiated power over all wavelengths (4×10^{46} ergs/sec) by the minimum lifetime of the source. The total energy in the system must be greater than that which is in the electrons because only a small fraction of the energy could have been pumped into the electron reservoir. The total energy of a QSS must be about 4×10^{61} ergs if a conversion efficiency of 1% for the energy transferred to the electrons is assumed. This is equivalent to the explosion of 3×10^9 solar masses of hydrogen, the mass of a small galaxy, by thermonuclear processes.

These mass and energy characteristics are so unlike anything previously encountered that astronomers questioned the distances of the QSS's, which are indicated by the measured red shifts. If the red shifts are not cosmological, the distances could be small and the total energies could be drastically reduced. But other explanations of the red shifts pose equally baffling problems. The only certain conclusion is that the detection of the quasi-stellar radio sources and the measurement of their red shifts is one of the most significant events of recent years in astronomy.

QUATERNARY, in geology, is the latest chapter in the earth's history and comprises the time that has elapsed from the end of the Pliocene (*q.v.*) to the present day. It is the second division of the Cenozoic era (*q.v.*) as indicated in the accompanying geologic time chart but represents such a short time that some geologists hesitate to give it equal rank and regard it as merely a subdivision of the preceding Tertiary period. Two divisions of the Quaternary period are usually recognized: (1) the Pleistocene,

the larger part; (2) and the Holocene or Recent, a short period following the Last Glaciation. For a brief history of the origin and application of the term see *GEOLOGY: Historical Geology: Paleontology and the Scale of Time*.

The Quaternary is characterized by wide climatic fluctuations. Compared with the Tertiary period, the climate was much colder: ice sheets developed in Scandinavia, on the higher mountain ranges of Europe and Asia and in North America. In the southern hemisphere the Antarctic ice, like that of Greenland, was larger and the Andes, Tasmania and New Zealand had important ice-caps. Hence the term Ice Age or Glacial period is often used for the Pleistocene, though the Holocene, usually called "post-glacial," may still be considered in the Ice Age.

The northern hemisphere probably had four separate ice advances; these ice advances comprise the major divisions of the Pleistocene. Elsewhere, Lower, Middle and Upper Pleistocene are paleontologically distinguished, though strict contemporaneity in different parts of the world has not been established. The Holocene is subdivided on the basis of its vegetational development (see *Vegetation*, below).

The beginning of the Quaternary is difficult to define since the transition from the last phase of the Tertiary (the Pliocene) was

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
CENOZOIC ERA			
Quaternary	Recent (last 11,000 years)	Early man	2+
	Pleistocene	Large carnivores	10
	Pliocene	Whales, apes, grazing forms	27
Tertiary	Miocene	Large browsing mammals	26
	Oligocene	Rise of flowering plants	55

Cambrian		Marine invertebrates	550-570
PRECAMBRIAN TIME			
		Few fossils	more than 3,400

in every respect gradual. Thus the gradation of animal life is imperceptible from the Late Pliocene into the Lower Pleistocene (Villafranchian). The onset of the First Glaciation is the event most widely accepted as marking the opening of the era.

This article deals with the stratigraphy and climate of the Pleistocene or glacial epoch of the Quaternary in Europe and Great Britain, the pluvial phases to the south of the glaciations and corresponding to them, the chronology, animal life and vegetation of the time up to the Recent or Holocene and briefly discusses the Quaternary as the age of man. For details of the glacial epoch in North America, its correlations with European and other regions and for a more detailed discussion of the extent and effects of glaciation, the glacial and interglacial ages and the life and climate of the epoch, see **PLEISTOCENE EPOCH**.

Stratigraphy.—A. Penck and E. Brückner in their classical work recognized four Alpine glaciations which they named in alphabetical and chronological order, Günz, Mindel, Riss and Würm. The glaciations were separated by three mild interglacial epochs, Günz-Mindel, Mindel-Riss and Riss-Würm. Of these, the Mindel-Riss or Great Interglacial was the longest: it lasted almost half the total length of the Quaternary. Some geologists subdivide the glaciations: the first three into two and Würm into three phases, the phases being separated by minor mild phases called interstadials. While the interglacial epochs were warmer than the present—the Great Interglacial was warmer by about 2.5° C.—the interstadials remained cold.

A vast Scandinavian ice sheet radiated outward over the Netherlands, against the northern slopes of the Hartz and Sudeten mountains and over the plains of Russia to the Urals and down the valleys of the Don and Dnieper. In Germany three glaciations, Elster, Saale and Weichsel, are recognized. A Warthe stage was intercalated between the Saale and Weichsel; whether it was a separate glaciation, a late phase of the Saale or an early phase of the Weichsel remains undecided. Weichsel is equated with the Alpine Würm, Saale with the Riss and Elster with the Mindel. No northern European equivalent of the Alpine Günz is definitely known, though Germany has indications of an Elbe or Baltic glaciation which preceded the Elster.

Britain was covered with ice as far south as the Bristol channel and the Thames valley; Ireland apparently was completely glaciated. In both countries the ice of the Last Glaciation (Newer drift) was much smaller in extent. The southern quarter of Ireland, parts of Wales, the Midlands, Derbyshire and Lincolnshire were also ice-free, though land ice in the North sea moved southward over Holderness to leave the Humber unobstructed. East Anglia, the classical region of the British Pleistocene, has the following succession: marine deposits called crags (see *Marine Animal Life*, below); North sea drift (Cromer till and Norwich brick earth); Great Chalky boulder clay; and Upper Chalky drift (with the Hunstanton boulder clay a product of the Warthe glaciation). The three intervening interglacial horizons are the Cromer forest bed; the Corton sands (Great Interglacial); Hoxne and other lake sites. Hoxne probably immediately preceded the Upper Chalky drift, though some writers place it in the Great Interglacial.

The North American ice sheet, unlike the ice masses of Europe, was mostly centred on low ground, namely, a Labrador centre east of and a Keewatin centre west of Hudson bay. Only in the west was the Cordilleran ice nurtured on high mountains. These coalescent ice sheets flowed northward to the Arctic ocean and southward across the Canadian boundary, extending as a group of vast lobes over the Great Lakes as far as St. Louis. As in Europe, four glaciations are usually distinguished, the Nebraskan, Kansan, Illinoian and Wisconsin. The Iowan, previously regarded as a separate glaciation or a late Illinoian phase, is now thought to have been the initial phase of the Wisconsin glaciation, corresponding perhaps to the European Warthe. The intervening interglacials are the Aftonian, Yarmouth (Great Interglacial) and Sangamon.

The Alpine Würm, North European Weichsel and British Newer drift are almost certainly contemporaneous. The correlation of the earlier glaciations is less certain; they are usually bracketed as shown in the accompanying table (interglacials in italics).

Alps	North Germany	British Isles	North America
Würm	Weichsel	Newer drift	Wisconsin
Riss Würm	Emilian sea	Hoxne	Sangamon
Riss	Saale	Great Chalky	Illinoian
Mindel-Riss	Holslein sea	Corton sands	Yarmouth
Mindel	Elster	North sea drift	Kansan
Günz Mindel	Mouster	Cromerian	Aftonian
Günz	Elbe?	Later crags	Nebraskan

Climate.—At the beginning of the Quaternary, the climate of temperate Europe appears to have resembled that of the present day. Considerable cooling took place during the Early Glaciation, sufficient to exterminate many Pliocene types of mammals and to enable arctic species to spread southward. But on the whole, the effect of the first Quaternary Glaciation was slight and in the Antepenultimate Interglacial (that of the Cromer forest bed of East Anglia) decidedly temperate conditions prevailed again. The Antepenultimate Glaciation, however, was more intense and it caused a sharp break in animal life. In a broad zone surrounding the ice sheets (periglacial zone) the climate became cold and pronouncedly continental. Tundra and steppe prevailed; from northern France to southern Russia a broadening belt of loess (windblown dust) was deposited. Those Pliocene elements in the animal life that had survived into the Antepenultimate Interglacial died out. The following Penultimate or Great Interglacial was a prolonged period of temperate climate, at times apparently milder than the present (e.g., *Rhododendron ponticum* in the Alps). The

Penultimate Glaciation, being much the same size as the Antepenultimate, had similar effects on the environment. By this time, however, many animals had adapted themselves to the recurrent phases of rigid climate and they assumed a Pleistocene aspect, with ancestral mammoth, woolly rhinoceros, etc. Man had also adapted his economy to the cold and stayed in the periglacial zone. The Last Interglacial witnessed a repetition of the mild conditions of the Great Interglacial. Fossil soils, animal life and vegetation suggest higher summer temperatures and an absence of frost. The Last Glaciation, though smaller than the preceding two, appears to have had pronounced climatic effects. Its periglacial zone was slightly smaller than that of the two preceding glaciations, but many interglacial mammals which had survived into the Last Interglacial (e.g., straight-tusked elephant, Merck's rhinoceros) became extinct and a most characteristic arctic animal life reigned north of the Alps. A second break in animal life is thus observed in the Quaternary at the beginning of the Last Glaciation. Since the Last Glaciation the climate has returned to the temperate conditions of the present day, with fluctuations for which the vegetation provides evidence.

Pluvials.—In the countries around the Mediterranean basin, including north Africa from Morocco to Egypt, pluvial phases corresponded to the glaciations. The anticyclonic conditions reigning over northern Europe forced more cyclones onto a Mediterranean course than is now the case; lakes were deeper and more widespread; the higher mountains, e.g., the Atlas, were clothed with ice; and the Mediterranean countries were covered with deciduous forests of the temperate type. Pluvial conditions occurred elsewhere on the polar side of the subtropical high pressure zones; e.g., in North America (Great basin), Asia and in the southern hemisphere in the three southern continents. Pluvials and glaciations are generally thought to have been coeval.

Sea Level.—The formation of large ice sheets, especially in Europe and North America, resulted in the withdrawal of a large amount of water from the oceans. The sea level therefore was low during the glacial and high during the interglacial phases. These fluctuations of the sea level are called eustatic. Evidence for low sea levels is provided by submerged terrestrial deposits (peats, etc.) and drowned river valleys; for high sea levels by traces of ancient shore lines (raised beaches) and terraces in the mouths of rivers. Raised beaches observed on coasts unaffected by tectonic movements or isostasy suggest two Pliocene phases: Calabrian and Sicilian, the latter about 80–100 m. above present sea level; and three interglacial phases: Milazzian (60 m.), Tyrrhenian (32 m.) and Monastirian (18–7.5 m.). The fact that the order in time is one of successively lower levels shows that the eustatic fluctuations are superimposed on a general and persistent drop in sea level which continued from the Tertiary into the Quaternary.

The volume of the Scandinavian icecap of the Last Glaciation has been estimated at 5,000,000 cu.km.; that of the icecap of North America at 21,000,000 cu.km. These masses, by their weight, depressed the ground covered by them. When the ice disappeared and its load was removed, the earth's crust responded elastically by plastic deformation and subcrustal flow and the regions recovered from the depression. This phenomenon is called isostasy. The isostatic rise of Scandinavia was over 300 m. and because of isostatic lag is still taking place at a maximum rate of 1 m. per century. In North America, the uplift was about 1,000 ft. and is also still continuing and tipping the waters of the Great Lakes southward.

Chronology.—Quaternary chronology usually rests on the succession of climatic phases which provide convenient divisions: glaciations, pluvials and phases of high sea level are also used as outlined in the preceding paragraphs. In many parts of the world, however, paleoclimatic evidence is very incomplete and paleontological divisions based on mammals and marine mollusks are used instead. Where prehistoric implements are abundant, chronologies of a more or less local nature have been based on them.

Many attempts have been made to develop an absolute chronology of the Quaternary: several depend upon the time rates of erosion, sedimentation and soil formation. In the Alps, Penck

arrived at 600,000 years for the Quaternary; other estimates extend the range to 1,000,000 or 2,000,000 years. A more elaborate time scale correlates the geologically established climatic phases with fluctuations of solar radiation caused by the perturbations of the earth's orbit. This method yields 600,000 years for the Quaternary, 190,000 for the Great Interglacial and 20,000 years for the interval since the Last Glaciation. This astronomical method, which may allow the dating of minor climatic phases, was conceived by J. Adhemar in 1842 and developed by the British scientists J. Croll and Sir Robert Ball in the second half of the 19th century. M. Milankovitch, from 1913 onward, undertook a recalculation of the astronomical tables. His theory, however, is not generally accepted and cannot be regarded as an explanation of the Ice Age as such.

Animal Life.—Terrestrial Animal Life.—The land animal assumed its modern character in the course of the Quaternary. This was due to three causes: (1) dying out of Tertiary elements; (2) appearance of new Pleistocene types; and (3) change of Pliocene forms into modern species by gradual evolution. It is noteworthy that in mammals, the lineages of which have been traced from the Villafranchian to the Holocene, the change in specific characters is slight; differences between Pliocene ancestors and Holocene descendants being no greater than differences between existing related species. In the Mollusca, which have been studied equally closely, these phylogenetic changes are even slighter and changes in the composition of the animals are chiefly the result of migration; e.g., the fresh-water shell *Corbicula* in the Pleistocene of Britain, now from Egypt southward.

Characteristic mammals of the European Villafranchian are: monkeys (*Macacus*), a cheetah, sabre-tooth tiger, zebra-like horses (*Equus stenonis*), Etruscan rhinoceros, tapir, primitive ox (*Leptobos*), mastodon, southern elephant; of the Lower Pleistocene: the same, except cheetah, tapir and *Leptobos*, but with red deer, elk (*Alces*), roe deer and a giant beaver (*Trogontherium*). Middle Pleistocene animal life is devoid of earlier exotic elements and new types appear which survive into the Upper Pleistocene. In the latter, the warm interglacial animal life and the cold glacial animal life have become more sharply separated. Interglacial species are the brown bear, beaver, Merck's rhinoceros, hippopotamus (west Europe), red deer, etc., straight-tusked elephant; glacial species are the arctic fox, varying hare, susliks (*Citellus*), lemmings, jerboa (loess steppe), true horses, woolly rhinoceros, reindeer, musk ox, mammoth, etc. Some of these became extinct before the Holocene began.

Marine Animal Life.—The marine animal life of the Quaternary shows slight evolution in the species, but there is evidence of much migration caused by climatic changes. The crags of East Anglia, which are Lower Pleistocene beach deposits rich in shells, illustrate this point. In the Sicilian (Mediterranean deposits of the Günz glacial stage), temperate shells like *Cyprina islandica* and the common whelk extended to the Mediterranean. The Tyrrhenian and Monastirian animal life (collectively called Tyrrhenian by paleontologists) is generally warmer than the modern ones, with the west African *Strombus bubonius* in the Mediterranean and *Astralinus rugosum* in the Channel Islands.

Vegetation.—The specific composition of the vegetation has changed much less than that of the animal life insofar as it is the result of phylogenetic evolution, though the shifting of vegetational zones in connection with climatic changes is a most characteristic phenomenon. With the growth of the ice sheets, the forest belts moved southward and tundra and cold steppe covered much of the periglacial zone. Each time the ice retreated, the vegetation belts moved northward again, producing a succession of plant associations which have been studied in peat deposits by means of pollen analysis, chiefly for the time since the Last Glaciation. The subdivisions of the Holocene make use of these changes in vegetation. Complicated divisions are now used in technical papers, but the classical scheme of Axel Blytt and R. Semander may, with modifications, still serve in summarizing the major features: (a) Subarctic phase (to c. 8,000 B.C.), treeless, with *Dryas octopetala*, dwarf willows and birches, interrupted by the mild Allerød Oscillation, when Scotch pine and tree birches appeared temporarily;

(b) Preboreal (8,000–7,000 B.C.), birch and pine immigrating; (c) Boreal (7,000–5,500 B.C.), with pine and birch dominating and alder, oak, lime and elm as subordinate, but increasing associates—later, hazel woods become prominent, climate continental; (d) Atlantic (5,500–2,000 B.C.), mixed oak forests culminate, hazel reduced to undergrowth, climate oceanic and in part warmer than at the present; (e) Subboreal (2,000–500 B.C.), climate begins to deteriorate, mixed oak forest retreats from the extreme limits reached, pine increases, but beech and hornbeam continue to spread north; (f) Subatlantic, mixed oak forest continues to retreat, beech culminates, present-day conditions.

Man.—The Quaternary is the age of man; in the 1960s it was almost certain that man originated in the Tertiary, his skeletal and industrial remains having been identified from Tertiary African deposits. Pithecanthropus of Java and Sinanthropus of China are of Lower Pleistocene age. In the Middle Pleistocene, types like Swanscombe man (from the lower Thames) are regarded by some authorities as closer to modern *Homo sapiens* than Neanderthal man, who is characteristic of the lower division of the Upper Pleistocene. In Europe, *Homo sapiens* appears around the second phase of the Last Glaciation as an immigrant from the south and east.

The cultural evolution of man in Quaternary times is evidenced by his implements, mostly of stone. At the beginning of the Pleistocene, very primitive tools (the human origin of which is debated) have been found in East Anglia. In the Antepenultimate Interglacial, the Chellean or Abbevillian hand-axe culture flourished and flake industries of the Clactonian variety appear. By Great Interglacial times, the Chellean had developed into the Acheulian which used the refined "wood technique" in manufacturing implements. The Clactonian persisted, but later the Levalloisian technique of making flakes from specially prepared cores marks another step forward in mental evolution. In the Last Interglacial, the Acheulian develops its final phase, the Micoquian; Levalloisian persists and from the fusion of these the Mousterian results, the culture of Neanderthal man par excellence. All these cultures are grouped together as Lower Palaeolithic. *Homo sapiens* brought with him the Upper Palaeolithic culture of blade industries (Aurignacian, Gravettian, Solutrian, Magdalenian) which flourished during the Last Glaciation. When the Holocene began, man had reached the Mesolithic stage; many of his stone tools were now composite, being made up of numerous hafted, small microliths.

In temperate Europe, the Mesolithic was replaced by the Neolithic which introduced agriculture, about 5,000 B.C. See ARCHAEOLOGY; MAN, EVOLUTION OF; see also references under "Quaternary" in the Index.

QUATERNIONS, a linear algebra consisting of four-dimensional vectors whose coordinates are any real numbers. The theory of this algebra was discovered by Sir William Rowan Hamilton in 1843 while he was trying, by analogy with the complex number representation of real two-dimensional vectors, to represent space vectors by the elements of a number system. For the definition of the algebra of quaternions and its place in the theory of algebras, see ALGEBRAS (LINEAR). Quaternions were intensively studied during the early part of the 20th century before the general theory of linear algebras came into being. Later.

they were usually thought of as a special case of such algebras. Their early importance lay in applications to geometry and mathematical physics. These applications later became a part of vector theory. See also VECTOR ANALYSIS; COMPLEX NUMBERS; NUMBER: *Quaternions and Hypercomplex Numbers*; NUMBERS, THEORY OF: *Algebras, and Their Arithmetics*. (A. A. AT.)

QUATORZAIN, the term used in English literature, as opposed to "sonnet," for a poem in 14 rhymed iambic lines closing (as the Italian sonnet never does) with a couplet. The distinction was long neglected, because the English poets of the 16th century had failed to apprehend the true form of the sonnet, and called Petrarch's and other Italian poets' sonnets quatorzains, and their own incorrect quatorzains sonnets. Almost all the so-called sonnets of the Elizabethan cycles, including those of William Shakespeare, Sir Philip Sidney, Edmund Spenser and Samuel Daniel, are really quatorzains. They consist of three quatrains of alternate rhyme, not repeated in the successive quatrains, and the whole closes with a couplet. See SONNET. (G. W. A.)

QUATRIN, sometimes spelled quartain, a piece of verse complete in four rhymed lines. The length or measure of the line is immaterial. This form has always been popular for use in the composition of epigrams, and may be considered as a modification of the Greek or Latin epigram. The commonest in English poetry is the ballad stanza, an outgrowth of the church hymn, in iambic metre rhyming *abcb*, with alternating four and three stresses to the line. Tennyson in "In Memoriam" used an iambic stanza rhyming *abba*. Though he did not invent it, it is often called the "In Memoriam" stanza. (G. W. A.)

QUCHAN (KUCHAN), a fertile and populous *shahrestan* (district) of the *ostan* (province) of Khurasan in Iran, is bounded on the north by the Turkmen Soviet Socialist Republic. The population, 171,856 in 1956, is principally composed of the descendants of the tribe of Zafaranlu Kurds which was established there, with a hereditary khan at its head, by Shah Abbas I in the 17th century. A large proportion are still nomads and live in tents in summer. The district produces much grain and there are extensive vineyards. The two chief towns are Quchan (pop. [1956] 21,250), 80 mi. (129 km.) NW of Meshed, and Shirvan (6,906), 40 mi. (64 km.) NW of Quchan. Quchan has suffered severely from repeated earthquakes; in that of 1893, 12,000 people are said to have perished. The present town was rebuilt after the last earthquake (1895) on a site 8 mi. (13 km.) E of the ruined town, 3,770 ft. (1,149 m.) above sea level, and is regularly laid out with broad streets and spacious bazaars. It is on the main road from Meshed to Ashkhabad on the Trans-Caspian Railway. On the nearby hill called Nadir-Tepe, Nadir Shah was killed in 1747.

(P. Z. C.; H. Bo.)

QUEBEC is the largest of Canada's ten provinces. Its population in 1961 was 5,259,211. Quebec city is the capital and Montreal is the major metropolitan centre, with a metropolitan population of 2,109,509. In the province are concentrated most of Canada's French-speaking people. They constitute approximately 81% of Quebec's population. The province is bounded on

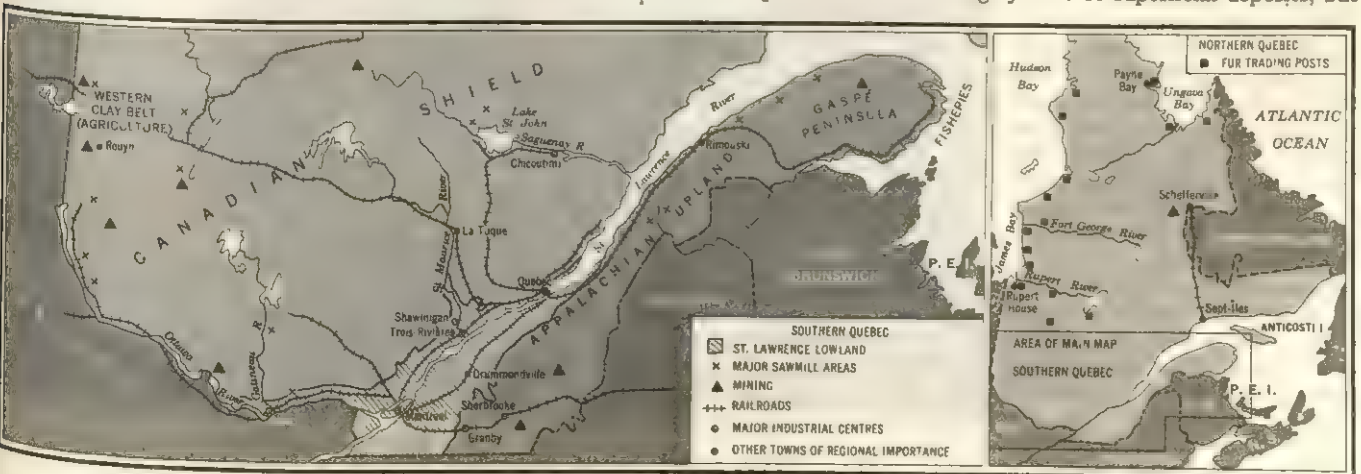

the southwest and west by part of Ontario, James bay and Hudson bay, on the north by Hudson strait and Ungava bay, on the east by the Coast of Labrador portion of Newfoundland and the Gulf of St. Lawrence, on the south by the Bay of Chaleur, New Brunswick, Maine, New Hampshire, Vermont, New York and part of Ontario. Its greatest extent is from the U.S. border, about 45° N., to Cape Wolstenholme, about 62° 30' N., and from Hudson bay, at a point about 79° 30' W., to Anse Sablon, about 57° W. The total area is 594,860 sq.mi. (1,540,689 sq.km.), or about one-sixth the total area of Canada. The area includes 71,000 sq.mi. (183,890 sq.km.) of fresh water.

PHYSICAL GEOGRAPHY

Quebec falls naturally into three well-defined regions. Over 90% of the province lies within the Canadian shield, a plateau-like area of crystalline Precambrian rocks whose surface declines northward from its high southern margin overlooking the St. Lawrence lowlands and the Gulf of St. Lawrence. The lowland region occupies a triangular area traversed by the St. Lawrence and Ottawa rivers, lying between the shield to the north and the Appalachian uplands to the southeast. The lowland decreases in width downstream, from 70 mi. (113 km.) in the vicinity of Montreal, to about 20 mi. (32 km.) at its apex at the Île d'Orléans below Quebec city. Anticosti Island is geologically part of the same region. The Appalachian uplands include the Eastern Townships of the southeastern part of the province, along the U.S. border, and Gaspé peninsula, and are part of the belt of Paleozoic fold mountains which extends from Alabama to Newfoundland.

The Canadian Shield.—Geologically, the Canadian shield is still incompletely known (see also PRECAMBRIAN TIME). The Precambrian rocks of which it is formed have been subjected to several periods of mountain building, as a result of which the ancient sedimentary rocks were strongly folded and faulted, intensely metamorphosed and intruded by masses of igneous rock. The deposition of minerals far below the surface was associated with the orogenies, and the processes of erosion, acting through prolonged periods, have laid bare the deposits, making them accessible for mining. Thus gold, copper and zinc are mined in the Noranda and Chibougamau areas. Contained within the early Proterozoic (late Precambrian) sediments of the Labrador trough, a folded and faulted belt extending southwest from Ungava bay for 600 mi. (966 km.), are extensive bodies of iron ore, which since 1954 have been mined at Schefferville. (See also LABRADOR-UNGAVA.)

A cover of Paleozoic sedimentary rocks formerly extended widely over the shield, and Paleozoic rocks have been preserved in the downfaulted Lake St. John depression. However, most of the sedimentary strata have been stripped away, leaving large areas of monotonous plateau lying between 1,500 and 1,900 ft. (457 and 579 m.) above sea level. The elevation of the plateau declines gently toward James, Hudson and Ungava bays, but drops to Hudson strait in cliffs over 1,000 ft. (305 m.) high. North of the tree line the plateau surface is largely bare of superficial deposits, but

SURFACE FEATURES, LAND USE AND INDUSTRIAL CENTRES OF QUEBEC

toward the south extensive areas are thickly covered with glacial deposits. Sinuous sandy ridges, or eskers, wind between the low forested morainic hills, and the intervening hollows are occupied by innumerable lakes and bogs. In western Quebec there is a belt of glacial clays, deposited in the Ice Age Lake Barlow-Ojibway, a great fresh-water lake impounded by the ice front during its retreat.

The irregular deposition of glacial deposits and the deepening of depressions by the erosive action of the ice served to disrupt the drainage pattern, and many of the rivers of the shield consist of series of lakes connected by falls or rapids, offering great potentialities for the development of hydroelectric power. The power potential of the rivers draining south is especially great, for they plunge from the plateau in deep gorgelike valleys down the dissected fault-line scarps which form the shield's southern margin. The crest of the scarp where it overlooks the estuary of the St. Lawrence lies at elevations of over 3,000 ft. (over 900 m.). The most spectacular break in the shield's rim is formed by the fjord of the lower Saguenay river, draining from Lake St. John. The great Shipshaw power stations utilize the force of the upper part of the river, near its exit from the lake. The St. Maurice river, with the Ottawa and its tributaries, have also been developed for power. Other rivers with developed or potential hydroelectric capacity include the Bersimis, Peribonca, Outardes and Manicouagan. The power supplies pulp and paper mills, which use logs floated down the rivers with the spring thaw.

The St. Lawrence Lowlands.—This region contrasts strongly with the shield. The bedrock is of sedimentary origin, great thicknesses of limestone, dolomite and shale of Cambrian, Ordovician and Silurian ages lying almost horizontally, with occasional faults, upon a basement of crystalline shield rocks. Bedrock is seldom exposed, except in the Monteregian hills, which are small intrusions of igneous rock of Devonian or later age, aligned eastward from Montreal. The surrounding strata have been worn down to a gently sloping surface, the Quebec platform, which rises downstream from about 100 ft. (31 m.) at Montreal to 300 ft. (91 m.) at Quebec city where Quebec citadel, an old French fort, was built, at the lip of the gorge incised into it by the St. Lawrence river (*q.v.*).

The St. Lawrence is possibly one of the most youthful of the major rivers of the world, having occupied its present course for only a few thousand years. During this geologically brief time it has been unable to eliminate the rapids which prevented navigation above Montreal. The St. Lawrence seaway (*q.v.*), opened in 1959, is the latest of a series of canal systems that have been built to avoid the rapids. The great Beauharnois power station utilizes the power of the St. Lawrence river.

During the Wisconsin (late Pleistocene) glacial period the lowlands were covered to a depth of several thousand feet by the ice sheet which spread out from the shield area. The great weight of ice depressed the earth's crust, and as the ice front retreated northward toward the close of the glacial period the lowlands lay below sea level and were occupied by a marine embayment named the Champlain sea. As the crust recovered from its depression the land emerged from the sea, carrying with it the covering of silts and sands which had been deposited on the sea floor. (See also **PLEISTOCENE EPOCH.**)

The Appalachian Uplands.

—The southeastern margin of the lowlands is marked by Logan's

line, or fault, a line of faulting which extends from east of Lake Champlain northward to the St. Lawrence river at Quebec city. Beyond Logan's line lie the folded rocks of the Appalachian region. These range in age from Cambrian to Carboniferous, and consist of great thicknesses of limestone, shale, sandstone and volcanic rocks which were deposited in a geosyncline and subjected to folding and faulting along northeast-trending axes in successive Paleozoic orogenies. The asbestos deposits of the eastern townships are associated with intrusions of ultrabasic rock, while granitic intrusions of the Gaspé peninsula have given rise to deposits of copper. Prolonged erosion has resulted in the reduction of the original mountainous relief in much of the region to a plateau about 1,200 ft. (366 m.) above sea level. In the Eastern Townships three parallel northeast-trending ranges rise above the plateau and include several summits of over 3,000 ft. (914 m.). The highest peak of Quebec province, Mt. Jacques Cartier, rises to 4,160 ft. (1,268 m.) in the Shickshock mountains of Gaspé peninsula.

The bold north coast of the peninsula contrasts with the south coast where the land declines gently beneath the waters of Chaleur bay. The picturesque inlets and promontories of the tip of the peninsula reflect the structural trend.

Glaciation resulted in the deepening of valleys, such as those occupied by Lakes Memphremagog, Témiscouata and Matapédia, and the mantling of the bedrock by glacial drift. The original forest cover has been cleared from half the area of the Eastern Townships, but from only a narrow coastal strip of the peninsula.

Climate.—The wide spread of latitude and the considerable distance from the Atlantic to the western parts of Quebec produce marked continental characteristics in the climate. In the centre of northern Quebec the range of temperature probably is as much as 70° F. (30° C.); along the St. Lawrence river at Montreal the monthly average temperature ranges from about 15° F. (–9° C.) in January to 70° F. (21° C.) in July. In July the isotherm of 57° F.—which determines the northern limit of the growth of crops—runs west-east through James bay. Hence it is the poor quality of the soils in southern Quebec rather than the temperatures that limits the northern extension of agriculture.

The outstanding feature of the climate is of course the constant passage of low-pressure eddies (cyclones) along the St. Lawrence. This results in an almost uniform type of rainfall in the southern part of the province, since these cyclones are the rain bringers in this part of the world. The weather, however, is quite variable since the front of such a cyclone gives warm moist winds from the south, while the rear is accompanied by cold dry winds from the north. The annual rainfall increases fairly regularly from 15

NORTHERN COAST OF THE GASPÉ PENINSULA

The rugged nature of this region contributes to its sparse population. Lumbering and fishing are the primary occupations.

in. (381 mm.) in the north to more than 40 in. (1,016 mm.) on the southern boundary of the province.

The snowfall in the high plateau behind Quebec (in the vicinity of the Laurentide provincial park) is perhaps the highest in the continent, and usually exceeds 120 in. (3,048 mm.) in winter. This in part accounts for the popularity of skiing in this part of Canada.

Plant and Animal Life.—The distribution of plant life is controlled largely by climate and may be divided into zones characterized by the arctic tundra north of the tree line; intermingled tundra and northern spruce forest grading into the subarctic lichen and coniferous woodland; the mixed forest of the St. Lawrence lowland; and the mixed and hardwood forest of the eastern townships and the Gaspé peninsula.

The province is rich in wildlife including barren-ground caribou, deer and beaver, mink and other fur-bearing animals. Birds are varied and numerous and game fish include trout, arctic char, bass, pike, pickerel and salmon. For additional details on plant and animal life see LABRADOR-UNGAVA.

Parks.—Quebec has six provincial parks, Saguenay (21,000 sq.mi. [54,392 sq.km.]), on the north shore of the St. Lawrence river in Saguenay county; La Vérendrye (4,746 sq.mi.), 140 mi. N.W. of Montreal; Laurentide (3,612 sq.mi.), 30 mi. N. of Quebec city; Mont Tremblant (1,223 sq.mi.), 80 mi. N. of Montreal and a well-known year-round resort area; Gaspesian (514 sq.mi.), on the Gaspé peninsula; and Mount Orford (15 sq.mi.), 15 mi. W. of Sherbrooke. There are in addition seven fish and game reserves, occupying more than 10,000 sq.mi. There is fishing in all of these except Mount Orford, and most provide some type of accommodations for tourists and sportsmen.

National historic parks in Quebec province are Fort Chambly, at Chambly and Fort Lennox, at Île aux Noix, near St. Johns. Places of historic interest in the cities of the province are described in the articles on the cities.

HISTORY

The great majority of the population of Quebec can trace their roots back to the 17th and early 18th centuries. New France had a population of approximately 65,000 in 1763 when it was ceded to Great Britain, and in the second half of the 20th century French Canadians were, with negligible exceptions, the descendants of these settlers. It is not surprising that history has great significance for Quebec's French-speaking majority; the provincial motto, *Je me Souviens* ("I remember"), is particularly apt.

France's interest in the new world began in the days of Jacques Cartier who wintered on the site of what is now Quebec city in 1535. The first permanent settlement, however, was established only in 1608 by Samuel de Champlain. At first population was sparse and life was attuned to the interests of the trading companies that were chartered by the French monarchy to exploit the new lands. But in 1663 New France was placed directly under government control and a highly paternalistic, if sometimes neglectful, type of rule began. Under Louis XIV and his vigorous minister Jean Baptiste Colbert, especially, New France grew as an exclusively Roman Catholic area of settlement, with a quasi-feudal system of land tenure and social stratification much less rigid and generous than that of France. Along the St. Lawrence valley, seigniories were divided into long strips of land each with a narrow frontage on the river. These and other marks of the pattern of landholding are still discernible.

Unlike English-speaking North Americans, those who came to live in New France were not the rebels and nonconformists of Europe, but a selected group of loyal, orthodox Frenchmen. They were ruled by a governor and intendant appointed by the king and watched over by a strong ecclesiastical authority represented by the bishop of Quebec and by religious orders, especially the Jesuits, who also carried out missionary activity of heroic proportions. Institutions of self-government were of minimal importance. Mercantilist principles governed the economic life of the colony and trading activity was subject to rigorous control. Life was rarely peaceful: war with Indians and the English colonies to the south was the rule rather than the exception. The community grew steadily, however, until the British conquest during the

French and Indian War (*q.v.*). The fortress city of Quebec fell to Gen. James Wolfe in 1759 and by the treaty of Paris, 1763, New France was ceded to Great Britain.

The full significance of the conquest is still a matter of debate among historians. It is difficult to determine how many of the characteristics of the post-conquest society in Quebec were a simple prolongation of earlier tendencies; how many were distortions induced by the trauma of defeat and alien rule. But there is little disagreement as to the broad features of Quebec life as it evolved in the late 18th and 19th centuries. French Canadians became firmly attached to an agrarian mode of life, centred about the parish, and leadership came predominantly from the clergy and the seigniorial class. The latter gradually gave way to members of the liberal professions, especially notaries and lawyers, but no strong commercial middle class emerged to challenge the English and Scottish merchants who controlled both external and, to a lesser extent, internal trade.

The conservative mood typical of French Canada until very recent times was well established by the end of the 18th century. The overriding collective goal could not be "progress" or expansion; it was survival. The preservation of the French language, the Roman Catholic religion and traditional ways of life (particularly the civil law which sanctioned French Canada's special pattern of private relationships) absorbed the attention and energies of the people and their leaders. The English vacillated for several decades between policies of anglicization and the acceptance of French particularism, but the Quebec act (*q.v.*) of 1774, which guaranteed to the French their civil code and the status of their religion, weighted the scales heavily in favour of survival. The support the early British governors gave to seigniorial and clerical leaders was sufficient to take the edge off dissatisfaction, and to assure that the American Revolution would evoke little response along the St. Lawrence valley. The French Revolution created even less of a ripple. Its radical, and especially its anticlerical, character made it anathema to the key elements of French Canadian society. The handful of *émigré* priests who brought tales of horror to the new world merely reinforced a profound distaste for this essentially urban and middle-class-oriented transformation in Europe. The majority of French Canadians from this time on viewed their ancestral home with dismay and mistrust and turned inward, relying on their own resources, even more resolutely.

Representative government came to Quebec in an unusual way. The French Canadian majority had little to do with its being granted. Indeed, its most prominent spokesmen heartily opposed the idea of an elective assembly. The Constitutional act of 1791, which authorized an elected lower house in a bicameral legislature, was rather a concession to the flood of Loyalists who, following the American Revolution, settled in the upper St. Lawrence valley and the eastern Great Lakes area, which became known as Upper Canada. These emigrants had a tradition of self-government and could not long be satisfied with rule by a governor and his appointed council. The Constitutional act thus divided the St. Lawrence valley settlements into two units—Upper Canada (the future Ontario) and Lower Canada (the future Quebec) and established parallel forms of government in each. (See CONSTITUTIONAL ACT, CANADIAN.) The English and Scottish merchants of Lower Canada who had clamoured for years for representation thus got their wish, but at a time and in a form which gave them little satisfaction as Lower Canada's assembly was elected by both Protestants and Catholics. From the outset it had a French Canadian majority that rapidly developed a point of view of its own.

The legislative assembly became the focal point of French Canada's struggle to assure its future and, as far as possible, control its own destiny. Within it the new secular elite of lawyers, notaries and other middle-class professionals came to the fore. Throughout the first three and a half decades of the 19th century, they fought interminable and indecisive skirmishes against the "chateau clique" of English administrators, merchants and land speculators, Church of England clergy and "collaborating" French officeholders that clustered around the British governor. A comparable battle was being waged against the governing clique called

BY COURTESY OF CONSULATE GENERAL OF CANADA, PHOTOGRAPH, GEORGE HUNTER

VIEW FROM THE NORTH OF QUEBEC CITY, CAPITAL OF THE PROVINCE OF QUEBEC

In the foreground is the Anglo-Canadian Paper company. In the upper centre are the Château Frontenac and the Citadel, two historic landmarks of the upper town

the "family compact" in Upper Canada, but there the racial overtones that complicated the Lower Canadian situation were absent, and a more clear-cut goal—responsible government, *i.e.*, an executive responsible to the majority in the elected assembly—was apparent. In both colonies, armed uprisings flared in 1837, but the causes and aims of the *patriotes* of Lower Canada were not identical with those of the Upper Canadian reformers. Lord Durham, the governor who was sent over to cope with the rebellions, may have underestimated the strength of social and political radicalism among the *patriotes*, but his famous comment on the Lower Canadian situation contained a large element of truth: "(I) found two nations warring in the bosom of a single state: I found a struggle, not of principles, but of races."

Lord Durham's epochal report recommended two main lines of settlement for the troubles in Canada: first, union of Upper and Lower Canada so as to place French Canadians in a minority position from which defense against assimilation would be difficult; secondly, the granting of responsible government to the new union regime. Only the first recommendation was acted upon immediately and another decade of struggle was necessary to achieve responsible government. The parliamentary fight for this goal created a remarkable unity between moderate reformers of both Canada East and Canada West (as Lower and Upper Canada were known after the act of union, 1840), but once achieved, the underlying differences between the French, Catholic, land-oriented majority of Canada East and the English, Protestant, commercially-oriented majority of Canada West reasserted themselves. Chronic political instability characterized the 1850s and 1860s.

The confederation of British North American colonies (Canada East and Canada West, Nova Scotia and New Brunswick) in 1867 brought an end to the union regime. One of the chief attractions of the newly formed Dominion of Canada to French Canadians was the fact that it gave to them control of a territorial unit, the province of Quebec, in which they had an assured majority and could elect a government with a defined autonomous jurisdiction. To some extent they shared the English-Canadian vision of a new nation stretching from the Atlantic to the Pacific, with a growing in-

ternal market and ample room for expansion. But a central concern was undoubtedly to assure cultural survival both by securing Quebec's right to control its own education, property and civil rights and local affairs and by obtaining guarantees for the status of the French language within the new central government, and education rights for Roman Catholics no matter where they lived in Canada.

In the years that followed confederation, Quebec developed qualities that made it unique among the provinces. Although French Canada's contribution to the life of the country as a whole was considerable (*e.g.*, two prime ministers: Sir Wilfrid Laurier [1896–1911] and Louis St. Laurent [1948–57]), it tended to look on Quebec as its special homeland. Divisions in outlook between the English-speaking majority and the French-speaking minority of Canada as a whole accentuated the importance of the province in which French Canadians predominated. Two sources of tension are worth noting. First, there were the "schools questions," which turned on the limitations on the

opportunities of French Roman Catholics to secure the education they desired in the western provinces and in Ontario. Secondly, there were the crises provoked by Canadian participation in overseas wars. There was some outcry from Quebec against the volunteer contingent that Canada sent in support of Great Britain's South African War campaign at the turn of the century, but French Canadian protests against conscription for overseas service during both World Wars I and II were much more bitter and created a profound division. On matters such as these, as well as in its consistent desire to maintain provincial rights in Canada's federal system, a special Quebec view evolved.

The degree to which French Canadians actually molded their own destinies even in the province of Quebec should not be exaggerated. Especially during the period beginning with World War I, Quebec was transformed from a primarily agricultural region to an industrial and urban one. The capital invested in industry, however, came largely from English, English Canadian and later U.S. sources, and the top positions in the economy were almost exclusively manned by English-speaking personnel. By the second half of the 20th century large enterprises were changing the face of the entire province and the share that French Canadians had in them was small. Political life remained the domain of French Canadians, however, and although the forces of urbanism and industrialism were reproducing in Quebec many of the general characteristics of North American civilization, French Canadian society did not lose its distinctiveness. See also CANADA: History.

GOVERNMENT

Political institutions in Quebec, as in the rest of Canada, follow the British parliamentary model. A premier and cabinet, responsible to the elected lower house of the legislature, carry on government in the name of the lieutenant governor, the queen's representative. Although contemporary Quebec is not noted for its enthusiasm for Canada's monarchical forms, the lieutenant governor's position, protected from change by the province under the

terms of the British North America act (q.v.) is the subject of little controversy. Its incumbent, appointed by the federal government, leads an unobtrusive existence, preoccupied with formalities and with few and waning real powers. Strong, indeed authoritarian, premiers have been the key political figures during the 20th century.

Alone among Canada's provinces, Quebec maintains a bicameral legislature. The upper chamber (legislative council) has 24 members nominated for life by the provincial government (lieutenant governor-in-council). It has, formally, powers which are equal to those of the elected legislative assembly, except in financial matters, but its debates rarely evoke public interest. The legislative assembly is composed of 95 members elected on the basis of universal suffrage from single-member constituencies. Women received the federal franchise in 1918, two years before women in the U.S., and the provincial franchise in 1940. The maximum life of a legislature is five years, but dissolution and a general election comes usually after four years. While procedures are broadly similar to those in other Canadian legislatures, special practices (e.g., in the use of the public and private bills committees) have developed over the years. Quebec's civil service, to which a high proportion of appointments have traditionally been made on a patronage basis, was subjected to extensive overhauling after the defeat of the Union Nationale in 1960, discussed below.

Political loyalties are strong, but a persistent element of French Canadian nationalism gives a particular cast even to the Quebec sections of the two long-established Canadian parties, Liberals and Conservatives. Nationalist "third parties" have been recurrent phenomena and, until the 1960s, they were the only alternative to the "old-line" parties which commanded extensive support. The Social Credit party, which succeeded in forming the government in two other Canadian provinces (Alberta and British Columbia), showed considerable strength under the leadership of R  al Caouette in the province of Quebec in the federal general elections of 1962 and 1963. Democratic socialist parties, such as the Co-operative Commonwealth federation and its successor the New Democratic party, have experienced great difficulty in Quebec.

Since 1896 the Liberal party has counted Quebec as one of its strongholds, especially for federal elections. From 1936 to 1960, however, a conservative nationalist party, the Union Nationale, controlled the provincial government except for a brief wartime return to the Liberals. The Union Nationale enjoyed from its inception the exceptionally powerful leadership of Maurice Duplessis (1890-1959). Although it had been elected originally on promises to eliminate corruption and political control by corporations and trusts, it quickly established a potent machine with close relations to the U.S. and English-Canadian business interests it had denounced. After its first election, its popular appeal was based on a strenuous defense of provincial rights and on the commanding personality of its leader. In spite of one or two clashes with church leaders, the Union Nationale gave strong support to the Roman Catholic Church and in turn benefited, as other regimes had done in the past, from church teaching which emphasized the respect due to authority.

More radical nationalist groups, such as that led by Marcel Chaput in the 1960s, have periodically aroused public interest in the proposition that Quebec separate from confederation and form an independent French state in North America.

Rapid industrialization and urbanization created a desire in some circles in the post-World War II period for provincial social and economic policies designed to ease the transition from rural patterns and to give recognition to the leaders of new social groups. Feelings such as these were largely pent up during the Union Nationale era. Duplessis' death in 1959 and the subsequent defeat of his party by the Liberals in June 1960 released a variety of forces for change. Pressures for educational reform and a greater role for the laity in schools and social institutions; for civil service reform; for the elimination of political corruption; for French Canadian control of industry through public ownership if necessary; for a redefinition of Quebec's status in the Canadian federal system, including a bigger share of total tax revenues—all these and more combined to create a dynamism that was unmistakable.

More than ever in the past, however, it was clear that Quebec's French Canadian majority expected the provincial government to play a vital role in the shaping of its social and economic future.

EDUCATION

Quebec's education system is complex, being divided on both religious and linguistic lines. Section 93 of the British North America act gives jurisdiction over education to the provinces of Canada, but provides protection for denominational schools that were established prior to confederation. Thus in Quebec, at both the primary and secondary school levels, a Protestant school structure has been constructed parallel to the Roman Catholic schools. Children from families that are neither Protestant nor Roman Catholic normally study in Protestant schools. Their parents do not, however, enjoy the same rights with respect to the control of schooling. The language of instruction in most Roman Catholic schools is French and in most Protestant schools it is English; but separate provisions are made for English-speaking Roman Catholics and, on a much smaller scale, for French-speaking Protestants.

During its early development, Quebec's system of education did not operate under the over-all control of a ministry of education, as in all other provinces. In 1964, however, an education reform act, following in large part the recommendations of a Royal Commission of Inquiry on Education, created such a ministry. Its authority is limited by a complex advisory and administrative structure. The Superior Council of Education, named after consultation with religious authorities and bodies representing parents, teachers, school administrators and socio-economic groups, can exert considerable influence. Two committees of the Council, one Catholic and one Protestant, must approve texts and curriculum for use in the dual denominational structure which is retained. The minister of education has under him not only a deputy-minister, but also two associate deputy-ministers, one of whom is named after consultation with the Catholic committee, the other after consultation with the Protestant committee. Boards of school commissioners or trustees at the local level, separated along denominational lines, have financial and administrative responsibilities. Complete gratuity was granted to pupils registered in elementary and secondary schools in 1961. For the organization of the two school systems, see CANADA: Education; see also SCHOOL ADMINISTRATION: *Sectarian Systems: Canada*.

In the field of higher education the French-Canadian universities are patterned on the French model: it is difficult to transfer from them to another Canadian university before graduation, but graduates can pursue advanced degrees in universities throughout North America and Europe. Scattered throughout Quebec (with at least one in every diocese) are scores of private, Roman Catholic "classical colleges," eight-year institutions, the first four years of which are at the secondary level and the second four at the college level; these colleges, with few exceptions run by and largely staffed by the clergy, constitute the faculty of arts in Laval university (founded 1852) in Quebec city or the University of Montreal (1876). There are separate classical colleges for men and women but the rest of the higher educational system is coeducational. The Universit   de Sherbrooke (1954), at Sherbrooke, is also a French-language Roman Catholic institution. Three other universities, Bishop's (Anglican; 1843) at Lennoxville and McGill (1821) and Sir George Williams (1929) in Montreal, all English-language, are similar in organization to U.S. universities. There are also opportunities for vocational and adult education through both public and private agencies.

Concern for the expansion of cultural activity and particularly for the survival and development of French culture led to the creation in 1961 of a ministry of cultural affairs. The establishment within it of a special bureau for the French language reflects French Canadians' disquiet over the quality of speech that is evolving in a predominantly English-speaking North American environment. Quebec Houses have been established abroad, notably in Paris, to further the province's ties with Europe. A provincial Arts council distributes grants, and literature is encouraged by government guarantees to book publishers.

HEALTH AND WELFARE

The department of health was organized in 1936. Its main divisions include a system of county health units and divisions of tuberculosis, epidemiology, laboratories, venereal diseases, sanitary engineering, mental health, occupational health, nutrition, health education, medical services to settlers and demography. Hospital insurance in the province became effective Jan. 1, 1961.

Public welfare programs come under the department of social welfare and the department of youth. The department of welfare includes the Quebec social allowances commission, responsible for assistance programs for needy mothers, the aged, blind, disabled and others; social assistance services with divisions of family welfare and assistance in the home; youth protection services; and teaching and training services, responsible for the standards of teaching and training in other institutions under the authority of the department.

POPULATION

The 1961 census was 5,259,211, mostly French Canadians. English-speaking people were mainly centred in the larger cities, in

Pontiac and Abitibi counties, where there were many new Canadians, the Saguenay and St. Maurice industrial areas, Gaspé and the Eastern Townships north of the New Hampshire and Vermont border.

THE ECONOMY

Quebec ranks second only to Ontario in manufacturing and mineral production. Approximately 30% of the value of Canadian manufactured goods is produced in the province. The most important single industry is pulp and paper. In terms of value, petroleum products, nonferrous metal smelting and refining, miscellaneous electrical apparatus and supplies and slaughtering and meat packing rank high. More employment, however, is provided by the primary textiles industry than by any other. Cottons, woollens, man-made fibres and fabrics, hosiery and knitted goods are produced and dyeing and finishing operations carried out. Another large employer is the aluminum industry. Quebec produces about 85% of Canada's tobacco, cigars and cigarettes. The province also accounts for 70% of women's factory clothing, cotton yarn and cloth and more than 50% of synthetic textiles.
